Removal and Installation

Removal

All vehicles

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

2.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

3. Remove the left-hand catalytic converter.
For additional information, refer to: [Catalytic Converter](#) (309-00A Exhaust System - TDV6 2.7L Diesel, Removal and Installation).

Left-hand drive vehicles

4. Make sure the alignment mark, on the steering gear pinion seal protection cover, is central to the steering gear pinion casting.

E42703

VUJ0002958

5.  **CAUTION:** Do not turn the steering wheel with the steering column lower shaft disconnected as damage to the clockspring and steering wheel switches may occur.

Remove the steering gear shaft pinch bolt.

6. Disconnect the power steering control valve actuator electrical connector.

7. Detach the steering gear.

8. Support the steering gear.

All vehicles

9. Release the EGR valve inlet tube.

- Remove and discard the clamp.

10. Remove the EGR inlet pipe.

11. Remove the LH turbocharger heat shield.

E51188

12. Remove the turbocharger support bracket.

E51187

13. Remove the turbocharger outlet pipe retaining bolt.

E66709

14. Disconnect the turbocharger outlet pipe.

E66710

15. Disconnect the turbocharger outlet pipe.

- Reposition the LH turbocharger outlet pipe.

E66708

16. Detach the crankshaft position (CKP) sensor wiring harness from the oil return tube retaining plate.

- 17.** Release the LH turbocharger oil return tube.
- Remove and discard the O-ring seal.
 - Install blanking caps to the exposed ports.

- 18.** Remove the LH turbocharger oil return tube.
- Remove and discard the gasket.
 - Install blanking caps to the exposed ports.

19. Disconnect the LH turbocharger intake tube.

20. Disconnect the turbocharger electrical connector.

21. Lower the vehicle.

22. Disconnect the LH turbocharger oil supply pipe.

- Remove and discard the copper sealing washer.
- Install blanking caps to the exposed ports.

23. Raise the vehicle.

24. Remove the LH turbocharger.

- Remove and discard the retaining nuts.
- Remove and discard the studs.
- Install blanking caps to the exposed ports.

Installation

All vehicles

1. Install the LH turbocharger.

- Remove and discard the blanking caps.
- Install new studs and nuts.
- Tighten to 23 Nm.

2. Lower the vehicle.

3. Connect the turbocharger oil supply tube.

- Remove and discard the blanking caps.
- Install a new copper sealing washer.
- Tighten to 30 Nm.

4. Raise the vehicle.

5. Connect the LH turbocharger electrical connector.

E51181

6. Connect the LH turbocharger intake tube.

7. Install the LH turbocharger oil return tube.

- Remove and discard the blanking caps.
- Install a new gasket.
- Tighten to 10 Nm.

E66705

8. Secure the LH turbocharger oil return tube.

- Remove and discard the blanking caps.
- Install a new O-ring seal.
- Tighten to 10 Nm.

E66706

9. Attach the CKP sensor wiring harness to the oil return tube retaining plate.

E66707

10. Install the turbocharger outlet pipe.

E66708

11. Install the turbocharger outlet pipe.

12. Install the LH turbocharger outlet pipe bolt.

- Tighten to 10 Nm.

13. Install the turbocharger support bracket.

- Tighten to 23 Nm.

14. Install the LH turbocharger heat shield.

- Tighten to 9 Nm.

15. Install the EGR inlet pipe.

- Tighten to 10 Nm.

16. Attach the EGR valve inlet tube.

- Install a new clamp.

E51799

Left-hand drive vehicles

17. Attach the steering gear.

- Tighten to 100 Nm.

Fuel Charging and Controls - V6 3.0L Petrol - Fuel Charging and Controls - Overview

Description and Operation

Overview

The fuel charging and control system comprises a fuel pump, [FPDM \(fuel pump driver module\)](#), fuel rail and six fuel injectors. The fuel pump supplies fuel from the tank, via a pipe routed along the outside of the [LH \(left-hand\)](#) chassis box section, to the fuel rail. Refer to: [Fuel Tank and Lines](#) (310-01B Fuel Tank and Lines - V6 3.0L Petrol, Description and Operation).

The fuel rail distributes the fuel equally to each of the fuel injectors. The fuel injectors, which are controlled by the [ECM \(engine control module\)](#), are installed in the fuel rail positioned in the center of the air intake manifold. Refer to: [Electronic Engine Controls](#) (303-14B Electronic Engine Controls - V6 3.0L Petrol, Description and Operation).

Fuel Charging and Controls - V6 3.0L Petrol - Fuel Charging and Controls - System Operation and Component Description

Description and Operation

System Operation

Operation of the fuel charging and control system is controlled by the [ECM \(engine control module\)](#).

Refer to: [Electronic Engine Controls](#) (303-14B Electronic Engine Controls - V6 3.0L Petrol, Description and Operation).

Component Description

Fuel Pump

E74571

ItemDescription

1	Electrical connector
2	Fuel pump module
3	Fuel level sensor
4	Fuel level float

The fuel pump module is mounted in the [RH \(right-hand\)](#) side of the fuel tank and delivers fuel at variable flow and pressure to the fuel rail, which supplies fuel to all fuel injectors. The fuel pump operation is regulated by the [FPDM \(fuel pump driver module\)](#), which is controlled by the [ECM](#).

Refer to: [Fuel Tank and Lines](#) (310-01A Fuel Tank and Lines - TDV6 2.7L Diesel, Description and Operation).

Fuel Pump Driver Module

E99541

The [FPDM](#) is used to control the speed of the fuel pump based upon the fuel demand of the engine. The [ECM](#) controls the [FPDM](#) in response to inputs from the [FRP \(fuel rail pressure\)](#) sensor, [MAP \(manifold absolute pressure\)](#) sensor, [MAF \(mass air flow\)](#) sensor and the [IAT \(intake air temperature\)](#) sensor. The [FPDM](#) is attached to the [RH](#) end of the evaporative emission canister, which is installed on the underside of the center floor pan, above the rear stabilizer bar.

The [ECM](#) sends a [PWM \(pulse width modulation\)](#) signal to the [FPDM](#). The frequency of the signal determines the duty cycle of the pump. The

[PWM](#) signal to the pump represents half the ON time of the pump. If the [ECM](#) transmits a 50% ON time, this drives the pump at 100%. If the [ECM](#) transmits a 5% ON time, the [FPDM](#) drives the pump at 10%. The [FPDM](#) will only turn the fuel pump ON if it receives a valid signal between 4% and 50%. To turn the fuel pump OFF, the [ECM](#) transmits a duty cycle signal of 75%.

The status of the [FPDM](#) is monitored by the [ECM](#). Any errors can be retrieved from the [ECM](#) using the Jaguar approved diagnostic system. The [FPDM](#) cannot be interrogated for diagnostic purposes.

Fuel Injectors

E47305

Six fuel injectors are installed in the fuel rail. Two O-rings seal each injector to the fuel rail. The fuel jets from the injectors are directed onto the back of the intake valves.

The injectors are electromagnetic solenoid valves controlled by the [ECM](#). Each injector contains a solenoid-operated needle valve, which is closed while the solenoid winding is de-energized. The solenoid winding is connected to a power feed from the main relay and to an earth through the [ECM](#). The [ECM](#) switches the earth to control the opening and closing of the needle valve. While the needle valve is open, fuel is sprayed into the cylinder intake tract onto the back of the intake valves. The [ECM](#) meters the amount of fuel injected by adjusting the time that the needle valve is open.

Electric Throttle

E47298

The electric throttle controls the engine torque and is located on the air intake manifold at the front of the engine. The main components are an electric throttle control valve, an [APP \(accelerator pedal position\)](#) sensor and the [ECM](#).

The [APP](#) sensor determines the driver demand to control throttle opening. This value is received by the [ECM](#) and the throttle is then opened to the correct angle by means of an integral electric motor. Sensors in the throttle body are used to determine the position of the throttle plate and the rate of change in its angle.

Refer to: [Electronic Engine Controls](#) (303-14B Electronic Engine Controls - V6 3.0L Petrol, Description and Operation).

Fuel Rail

E93967

ItemDescription

1	Fuel injector
2	Fuel rail
3	FRP sensor
4	Fuel rail pressure damper
5	Fuel temperature sensor
6	Fuel supply pipe

The fuel rail maintains a fuel pressure of typically 4.5 bar (65 lbf/in²), however, this pressure will vary depending on engine requirements; lower at idle, higher at full load. Three fuel injectors are installed in each cylinder head and are connected to the fuel rail. O-ring seals are used to seal the injectors to the fuel rail.

Fuel Pressure Damper

E74573

A fuel pressure damper is attached to the fuel rail. The damper acts to damp pressure pulses from the fuel pump.

Fuel Temperature Sensor

E47606

The fuel temperature sensor is located in the fuel supply pipe at the front of the engine. The sensor is an [NTC \(negative temperature coefficient\)](#) sensor, which is connected to the [ECM](#) by two wires.
Refer to: [Electronic Engine Controls](#) (303-14B Electronic Engine Controls - V6 3.0L Petrol, Description and Operation).

Fuel Rail Pressure Sensor

E58945

The [FRP](#) sensor continuously monitors the fuel pressure in the fuel rail. This value is used by the [ECM](#) to calculate the injector pulse-width required to deliver the correct mass of fuel per injection. The [ECM](#) also uses this information to demand a specific fuel flow-rate from the fuel pump via the [FPDM](#).
Refer to: [Electronic Engine Controls](#) (303-14B Electronic Engine Controls - V6 3.0L Petrol, Description and Operation).

Fuel Charging and Controls - V6 3.0L Petrol - Fuel Charging and Controls

Diagnosis and Testing

Principles of Operation

For a detailed description of the petrol engine fuel charging and controls system, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

- [Fuel Charging and Controls](#) (303-04C Fuel Charging and Controls - V6 3.0L Petrol, Description and Operation),
- [Fuel Charging and Controls](#) (303-04C Fuel Charging and Controls - V6 3.0L Petrol, Description and Operation),
- [Fuel Charging and Controls](#) (303-04C Fuel Charging and Controls - V6 3.0L Petrol, Description and Operation),
- [Fuel Charging and Controls](#) (303-04D Fuel Charging and Controls - V8 4.2L Petrol, Description and Operation),
- [Fuel Charging and Controls](#) (303-04D Fuel Charging and Controls - V8 4.2L Petrol, Description and Operation),
- [Fuel Charging and Controls](#) (303-04D Fuel Charging and Controls - V8 4.2L Petrol, Description and Operation),
- [Fuel Charging and Controls](#) (303-04E Fuel Charging and Controls - V8 S/C 4.2L Petrol, Description and Operation),
- [Fuel Charging and Controls](#) (303-04E Fuel Charging and Controls - V8 S/C 4.2L Petrol, Description and Operation),

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Fuel level ● Fuel leaks ● Damaged fuel lines ● Damaged push connect fittings ● Fuel contamination/grade/quality ● Throttle body ● Damaged fuel tank filler pipe cap ● Damaged fuel tank filler pipe 	<ul style="list-style-type: none"> ● Fuses ● Loose or corroded electrical connectors ● Harnesses ● Sensor(s) ● Engine Control Module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident and there are clear symptoms refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Engine cranks, but does not fire	<ul style="list-style-type: none"> ● Engine breather system disconnected/restricted ● Ignition system ● Fuel system ● Electronic engine control 	Ensure the engine breather system is free from restriction and is correctly installed. Check for ignition system, fuel system and electronic engine control DTCs and refer to the relevant DTC Index
Engine cranks and fires, but will not start	<ul style="list-style-type: none"> ● Evaporative emissions purge valve ● Fuel pump ● Spark plugs ● HT short to ground (tracking) check rubber boots for cracks/damage ● Ignition system 	Check for evaporative emissions, fuel system and ignition system related DTCs and refer to the relevant DTC Index

Poor throttle response	<ul style="list-style-type: none"> Breather system disconnected/restricted Electronic engine control Transmission malfunction Traction control event Air leakage 	Ensure the engine breather system is free from restriction and is correctly installed. Check for electronic engine controls, transmission and traction control related DTCs and refer to the related DTC Index. Check for air leakage in intake air system

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• NOTE: If the control module/component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines that involve pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

4	-	Fuel supply pipe
5	-	Electric throttle body
6	-	Fuel supply cross over pipe

OVERVIEW

The fuel charging and control system comprises a fuel pump, fuel pump driver module (FPDM), fuel rails and 8 injectors. The fuel pump supplies fuel from the tank, via a pipe routed along the outside of the left hand chassis box section, to the fuel rail. The fuel rail distributes the fuel equally to each of the 8 injectors. The fuel injectors, which are controlled by the engine control module (ECM), are installed in the fuel rails on each side of the air intake manifold. A cross over pipe connects the 2 fuel rails together at the front of the engine. For additional information, refer to:

Fuel Tank and Lines (310-01C, Description and Operation),

Electronic Engine Controls (303-14C, Description and Operation).

Fuel Charging and Controls - 4.2L NA V8 - AJV8 - Fuel Charging and Controls - Overview

Description and Operation

Overview

The fuel charging and control system comprises a fuel pump, [FPDM \(fuel pump driver module\)](#), fuel rails and eight fuel injectors. The fuel pump supplies fuel from the tank, via a pipe routed along the outside of the left hand chassis box section, to the fuel rail. The fuel rail distributes the fuel equally to each of the fuel injectors. The fuel injectors, which are controlled by the [ECM \(engine control module\)](#), are installed in the fuel rails on each side of the air intake manifold. A cross over pipe connects the two fuel rails together at the front of the engine. Refer to: [Fuel Tank and Lines](#) (310-01 Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Charging and Controls - 4.2L NA V8 - AJV8 - Fuel Charging and Controls - System Operation and Component Description

Description and Operation

System Operation

Operation of the fuel charging and control system is controlled by the [ECM \(engine control module\)](#).

Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Component Description

Fuel Pump

E74571

ItemDescription

1	Electrical connector
2	Fuel pump module
3	Fuel level sensor
4	Fuel level float

The fuel pump module is mounted in the **RH (right-hand)** side of the saddle type fuel tank and delivers fuel at variable flow and pressure to the fuel rails, which supply fuel to all fuel injectors. The fuel pump operation is regulated by the [FPDM \(fuel pump driver module\)](#), which is controlled by the [ECM](#).

Refer to: [Fuel Tank and Lines](#) (310-01 Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Pump Driver Module

E99541

The [FPDM](#) is used to control the speed of the fuel pump based upon the fuel demand of the engine. The [ECM](#) controls the [FPDM](#) in response to inputs from the [FRP \(fuel rail pressure\)](#) sensor, [MAP \(manifold absolute pressure\)](#) sensor, [MAF \(mass air flow\)](#) sensor and the [IAT \(intake air temperature\)](#) sensor. The [FPDM](#) is attached to the [RH](#) end of the evaporative emission canister, which is installed on the underside of the center floor pan, above the rear stabilizer bar.

The [ECM](#) sends a [PWM \(pulse width modulation\)](#) signal to the [FPDM](#), the frequency of the signal determines the duty cycle of the pump. The [PWM](#) signal to the pump represents half the ON time of the pump. If the [ECM](#) transmits a 50% ON time, this drives the pump at 100%. If the [ECM](#) transmits a 5% ON time, the [FPDM](#) drives the pump at 10%. The [FPDM](#) will only turn the fuel pump ON if it receives a valid signal between 4% and 50%. To turn the fuel pump OFF, the [ECM](#) transmits a duty cycle signal of 75%.

The status of the [FPDM](#) is monitored by the [ECM](#). Any errors can be retrieved from the [ECM](#) using the Jaguar approved diagnostic system. The [FPDM](#) cannot be interrogated for diagnostic purposes.

Fuel Injectors

E47305

Eight, top fed, 12 hole, fuel injectors are installed in the fuel rails. Two O-rings seal each injector to the fuel rails. The fuel jets from the injectors are directed onto the back of the intake valves.

The injectors are electromagnetic solenoid valves controlled by the [ECM](#). Each injector contains a solenoid-operated needle valve, which is closed while the solenoid winding is de-energized. The solenoid winding is connected to a power feed from the main relay and to an earth through the [ECM](#). The [ECM](#) switches the earth to control the opening and closing of the needle valve. While the needle valve is open, fuel is sprayed into the cylinder intake tract onto the back of the intake valves. The [ECM](#) meters the amount of fuel injected by adjusting the time that the needle valve is open.

The solenoid winding of the fuel injector has a resistance of 13.8 ± 0.7 ohms @ 20 °C (68 °F).

Electric Throttle

E47298

The electric throttle controls the engine torque and is located on the induction elbow at the front of the engine. Its main

components are an electric throttle control valve, an APP (accelerator pedal position) sensor and the ECM.

The APP sensor determines the driver demand to control throttle opening. This value is received by the ECM and the throttle is then opened to the correct angle by means of an integral electric motor. Sensors in the throttle body are used to determine the position of the throttle plate and the rate of change in its angle. Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Rails

E74572

ItemDescription

1	FRP sensor
2	Fuel rail pressure damper
3	Fuel rail
4	Fuel rail temperature sensor
5	Fuel rail
6	Fuel rail pressure damper
7	Fuel rail inlet
8	Fuel rail connection pipe
9	Fuel injector

Each fuel rail maintains a fuel pressure of typically 4.5 bar (65 lbf/in²), however, this pressure will vary depending on engine requirements; lower at idle, higher at full load. Four fuel injectors are installed in each cylinder head and are connected to the related fuel rail. O-ring seals are used to seal the injectors to the fuel rails.

Fuel Pressure Damper

E74573

A fuel pressure damper is attached centrally to each of the fuel rails. The damper acts to damp pressure pulses from the fuel pump.

Fuel Temperature Sensor

E47606

The fuel temperature sensor is located in the rear of the [RH](#) fuel rail. The sensor is a [NTC \(negative temperature coefficient\)](#) sensor, which is connected to the [ECM](#) by two wires. Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Rail Pressure Sensor

E58945

The [FRP](#) sensor continuously monitors the fuel pressure in the fuel rail. This value is used by the [ECM](#) to calculate the injector pulse-width required to deliver the correct mass of fuel per injection. The [ECM](#) also uses this information to demand a specific fuel flow-rate from the fuel pump via the [FPDM](#). Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Charging and Controls - 4.2L NA V8 - AJV8 - Fuel Charging and Controls

Diagnosis and Testing

Principles of Operation

For a detailed description of the petrol engine fuel charging and controls system, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

[Fuel Charging and Controls](#) (303-04A Fuel Charging and Controls - 4.2L NA V8 - AJV8, Description and Operation),

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Fuel level ● Fuel leaks ● Damaged fuel lines ● Damaged push connect fittings ● Fuel contamination/grade/quality ● Throttle body ● Damaged fuel tank filler pipe cap ● Damaged fuel tank filler pipe 	<ul style="list-style-type: none"> ● Fuses ● Loose or corroded electrical connectors ● Harnesses ● Sensor(s) ● Engine Control Module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident and there are clear symptoms refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Engine cranks, but does not fire	<ul style="list-style-type: none"> ● Engine breather system disconnected/restricted ● Ignition system ● Fuel system ● Electronic engine control 	Ensure the engine breather system is free from restriction and is correctly installed. Engine detonates/knocks	<ul style="list-style-type: none"> ● Fuel pump/lines ● Air leakage ● Electronic engine controls ● Sticking VCT hub 	Check for fuel system failures. Check for air leakage in intake air system. Check for electronic engine controls and VCT system related DTCs and refer to the relevant DTC Index
No throttle response	<ul style="list-style-type: none"> ● Electronic engine controls ● Throttle motor 	Check for electronic engine controls and throttle system related DTCs and refer to the relevant DTC Index
Poor throttle response	<ul style="list-style-type: none"> ● Breather system disconnected/restricted ● Electronic engine control ● Transmission malfunction ● Traction control event ● Air leakage 	Ensure the engine breather system is free from restriction and is correctly installed. Check for electronic engine controls, transmission and traction control related DTCs and refer to the related DTC Index. Check for air leakage in intake air system

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• NOTE: If the control module/component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines that involve pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Removal and Installation

Removal

• WARNINGS:

This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

After carrying out repairs, the fuel system must be checked visually for leaks. Failure to follow this instruction may result in personal injury.

Do not carry or operate cellular phones when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the fuel injection supply manifold.
For additional information, refer to: [Fuel Injection Supply Manifold](#) (303-04A Fuel Charging and Controls - 4.2L NA V8 - AJV8, Removal and Installation).
3. Remove the injector retaining clips.

4. Remove the fuel injectors.

- Remove and discard the O-ring seal.
- Repeat the above procedure for the remaining injectors.

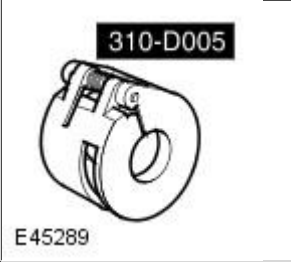

Installation

1. To install, reverse the removal procedure.

- Disconnect the quick release connector.
- Disconnect the electrical connector.

7. Using the special tool, disconnect the fuel line.

8. Disconnect the fuel rail pressure (FRP) sensor electrical connector.

9. Disconnect the FRP sensor vacuum line.

10. Disconnect the fuel temperature sensor electrical connector.

11. Disconnect the 8 fuel injector electrical connectors.

12.  **CAUTION:** Before disconnecting or removing the components, make sure the area around the joint faces and connections are clean. Plug open connections to prevent contamination.

Remove the fuel injection supply manifold.

- Remove the 4 Torx bolts.
- Remove and discard the 8 O-ring seals.

13. **NOTE:** Do not disassemble further if the component is removed for access only.

Remove the fuel injector.

- Remove the clip.
- Remove and discard the O-ring seal.
- Repeat the above procedure for the remaining injectors.

14. Remove the FRP sensor.

- Remove the 2 bolts.
- Remove and discard the O-ring seal.

15. Remove the fuel temperature sensor.

Installation

1. To install, reverse the removal procedure.
2. Tighten to 7 Nm.

3. Tighten to 5 Nm.

E98867

4. Tighten to 10 Nm.

E64435

5. Tighten to 6 Nm.

6. Tighten to 6 Nm.

Fuel Charging and Controls - 4.2L NA V8 - AJV8 - Fuel Pressure Regulator

Removal and Installation

Removal

• WARNINGS:

Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

The fuel system remains pressurized for a long time after the ignition is switched off. The fuel pressure must be relieved before attempting any repairs. Failure to follow these instructions may result in personal injury.

This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

1. Remove the engine cover.

For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Oramentation, Removal and Installation).

2. Depressurize the fuel system.

For additional information, refer to: [Fuel System Pressure Release - 3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8](#) (310-00 Fuel System - General Information, General Procedures).

3. Disconnect the fuel pressure regulator electrical connector and vacuum hose.

4. Remove the fuel pressure regulator.

- Remove and discard the O-ring seals.

E98867

Installation

1. NOTE: Install new O-ring seals.

To install, reverse the removal procedure.

- Tighten to 10 Nm.

Fuel Charging and Controls - 4.2L NA V8 - AJV8 - Throttle Body

Removal and Installation

Removal

1. Remove the engine cover.
For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
2. Remove the air intake duct.

- Release the 2 clips.
- Disconnect the breather hose.

E92642

3. Disconnect the throttle position (TP) sensor electrical connector.

E63455

E61748

4. Release the throttle body.

- Remove the 4 bolts.
- Remove and discard the throttle body gasket.

E61750

5.  **WARNING:** Since injury such as scalding could be caused by escaping steam or coolant, do not remove the filler cap from the coolant expansion tank while the system is hot.

- **NOTE:** Do not disassemble further if the component is removed for access only.

Disconnect the coolant hoses from the throttle body.

- Clamp the throttle body coolant hoses to minimize coolant loss.
- Release the throttle body hose clips

Installation

1. Connect the coolant hoses to the throttle body.

- Remove the hose clamps from the throttle body hoses.
- Secure the throttle body hoses clips.

2. Install the throttle body.

- Clean the component mating faces.
- Install a new gasket.
- Tighten the 4 bolts to 10 Nm (7 lb.ft).

3. Connect the TP sensor electrical connector.

4. Install the intake air duct.

- Tighten the clips.
- Connect the breather hose.

5. Install the engine cover.

For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornammentation, Removal and Installation).

6. Check and top-up the coolant.

Fuel Charging and Controls - 4.2L SC V8 - AJV8 - Fuel Charging and Controls - Overview

Description and Operation

Overview

The fuel charging and control system comprises a supercharger and air induction system, fuel pump, [FPDM \(fuel pump driver module\)](#), fuel rails and fuel injectors. The fuel pump supplies fuel from the tank, via a pipe routed along the outside of the [LH \(left-hand\)](#) chassis box section, to the fuel rail. The fuel rail distributes the fuel equally to each of the fuel injectors. The fuel injectors, which are controlled by the [ECM \(engine control module\)](#), are installed in the fuel rails on each side of the intercoolers. A cross over pipe connects the two fuel rails together at the front of the engine. The supercharger delivers compressed air into the engine through the air induction system.

Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Charging and Controls - 4.2L SC V8 - AJV8 - Fuel Charging and Controls - System Operation and Component Description

Description and Operation

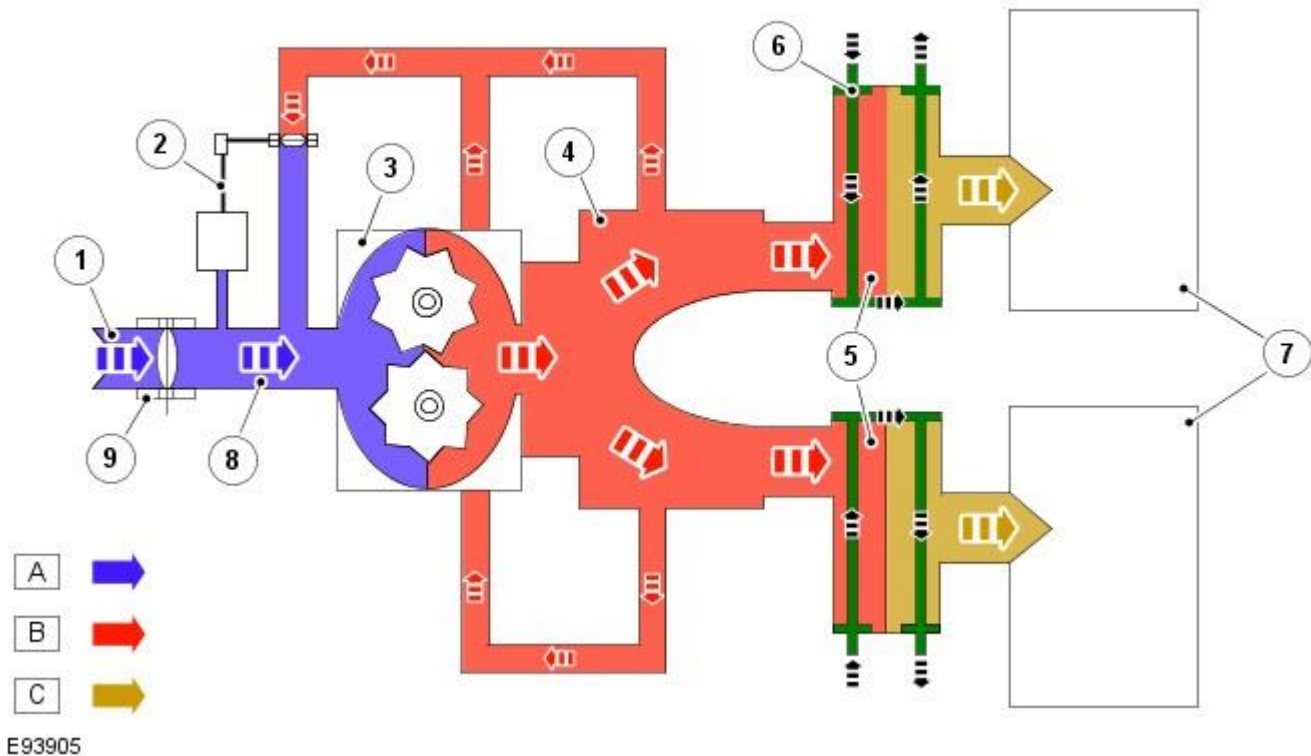

System Operation

Operation of the fuel charging and control system is controlled by the [ECM \(engine control module\)](#).

Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Component Description

Air Induction System

ItemDescription

1	Air inlet duct
2	Vacuum operated by-pass valve assembly
3	Supercharger
4	Supercharger exit port
5	Intercoolers
6	Cooling water
7	Cylinder heads
8	Induction elbow
9	Electronic throttle body

The air induction system comprises the supercharger and a series of ducts and ports which direct compressed air into the engine. Air is drawn into the engine through the air inlet duct and into the induction elbow at the back of the engine, which houses the electronic throttle. The air is directed through the induction elbow into the supercharger, where it is compressed above atmospheric pressure. The compressed air exits the supercharger through a port in the upper surface and through the charge air ducts into the two intercoolers, one above each cylinder bank.

After compression in the supercharger, the intake air temperature often exceeds 160 °C (320 °F). For this reason the intercoolers are liquid cooled and act as separate air to liquid heat exchanger matrices for each bank of cylinders. The cooled and denser compressed air passes from the intercoolers to the fuel rail adapters and into the engine.

A vacuum operated bypass valve, situated downstream of the throttle body, opens during part throttle operation. This has the effect of recirculating and controlling the compressed air pressure and reducing unnecessary supercharger pumping operation.

Fuel Pump

E74571

ItemDescription

1	Electrical connector
2	Fuel pump module
3	Fuel level sensor
4	Fuel level float

The high flow rate fuel pump module is mounted in the **RH (right-hand)** side of the saddle type fuel tank and delivers fuel at variable flow and pressure to the fuel rails, which supply fuel to all fuel injectors. The fuel pump operation is regulated by the **FPDM (fuel pump driver module)**, which is controlled by the **ECM**.

Refer to: [Fuel Tank and Lines](#) (310-01 Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Pump Driver Module

E99541

The **FPDM** is used to control the speed of the fuel pump based upon the fuel demand of the engine. The **ECM** controls the **FPDM** in response to inputs from the **FRP (fuel rail pressure)** sensor, **MAP (manifold absolute pressure)** sensor, **MAF (mass air flow)** sensor and the **IAT (intake air temperature)** sensor. The **FPDM** is attached to the **RH** end of the evaporative emission canister, which is installed on the underside of the center floor pan, above the rear stabilizer bar.

The **ECM** sends a **PWM (pulse width modulation)** signal to the **FPDM**, the frequency of the signal determines the duty cycle of the pump. The **PWM** signal to the pump represents half the ON time of the pump. If the **ECM** transmits a 50% ON time this drives the pump at 100%. If the **ECM** transmits a 5% ON time the **FPDM** drives the pump at 10%. The **FPDM** will only turn the fuel pump ON if it receives a valid signal between 4% and 50%. When the **ECM** requires the fuel pump to be turned OFF, it transmits a duty cycle signal of 75%.

The status of the **FPDM** is monitored by the **ECM**. Any errors can be retrieved from the **ECM** using the Jaguar approved diagnostic system. The **FPDM** cannot be interrogated for diagnostic purposes.

Fuel Injectors

E47305

Eight, top fed, 12 hole, fuel injectors are installed in the fuel rails. Two O-rings seal each injector to the fuel rails. The fuel jets from the injectors are directed onto the back of the intake valves.

The injectors are electromagnetic solenoid valves controlled by the [ECM](#). Each injector contains a solenoid-operated needle valve, which is closed while the solenoid winding is de-energized. The solenoid winding is connected to a power feed from the main relay and to an earth through the [ECM](#). The [ECM](#) switches the earth to control the opening and closing of the needle valve. While the needle valve is open, fuel is sprayed into the cylinder intake tract onto the back of the intake valves. The [ECM](#) meters the amount of fuel injected by adjusting the time that the needle valve is open.

The solenoid winding of the fuel injector has a resistance of 13.8 ± 0.7 ohms @ 20 °C (68 °F).

Electric Throttle

E47298

The electric throttle controls the engine torque and is located on the induction elbow at the rear of the engine. Its main components are an electronic throttle control valve, an [APP \(accelerator pedal position\)](#) sensor and the [ECM](#).

The [APP](#) sensor determines the driver demand to control throttle opening. This value is received by the [ECM](#) and the throttle is then opened to the correct angle by means of an integral electric motor. Sensors in the throttle body are used to determine the position of the throttle plate and the rate of change in its angle.

Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Rails

E93906

ItemDescription

1	RH fuel rail
2	RH fuel pressure damper
3	Fuel temperature sensor
4	FRP sensor
5	Fuel supply
6	LH (left-hand) fuel pressure damper
7	LH fuel rail
8	Fuel injectors (8 off)
9	Fuel supply cross over pipe

Each fuel rail maintains a fuel pressure of typically 4.5 bar (65 lbf/in²), however, this pressure will vary depending on engine requirements; lower at idle, higher at full load. Four fuel injectors are installed in each cylinder head and are connected to the fuel rail. O-ring seals are used to seal the fuel injectors to the fuel rails.

Fuel Pressure Damper

E74573

A fuel pressure damper is attached centrally to each of the fuel rails. The damper acts to damp pressure pulses from the fuel pump.

Fuel Temperature Sensor

E47606

The fuel temperature sensor is located in the rear of the [RH](#) fuel rail. The sensor is a [NTC \(negative temperature coefficient\)](#) sensor, which is connected to the [ECM](#) by two wires.

Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Fuel Rail Pressure Sensor

E58945

The [FRP](#) sensor continuously monitors the fuel pressure in the fuel rail, this value is used by the [ECM](#) to calculate the injector pulse-width required to deliver the correct mass of fuel per injection. The [ECM](#) also uses this information to demand a specific fuel flow-rate from the fuel pump via the [FPDM](#).

Refer to: [Electronic Engine Controls](#) (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Accessory Drive - TDV6 2.7L Diesel - Accessory Drive - Overview

Description and Operation

Overview

The combined crankshaft pulley and torsional vibration damper drives a single, 6-ribbed vee belt. The belt drives all of the engine-mounted accessories such as the generator, the power steering pump, the [A/C \(air conditioning\)](#) compressor and the coolant pump.

The accessory drive belt, which is a maintenance free poly-V type belt, is automatically pre-loaded by the belt tensioner and routed over idlers in order to maintain sufficient adhesion about the drive wheels. This ensures slip-free drive of the accessory components.

The torsional vibration damper incorporates compressed rubber between its inner and outer diameters to absorb vibration and shock loads.

The belt tensioner is calibrated to provide the correct amount of tension to the belt for a given drive system. Unless a spring within the tensioner assembly breaks, or some other mechanical part of the tensioner fails, there is no need to check the tensioner for correct tension.

The accessory drive belt should be inspected at every routine service for excessive wear and damage.

Belt tensioner

The belt tensioner consists of an idler pulley, which is free to rotate on a bearing located at the end of a spring-loaded pivot arm.

The accessory drive belt wear indicators are incorporated on the bottom of the accessory drive belt tensioner. When the indicators are aligned the accessory drive belt requires replacing.

Accessory Drive - TDV6 2.7L Diesel - Accessory Drive

Diagnosis and Testing

Principles of Operation

The 2.7L diesel engine uses two accessory drive systems, the Front End Accessory Drive (FEAD), and the fuel injection pump drive.

FEAD Belt

The FEAD belt drives: the coolant pump, the generator, the power assisted steering pump and the air conditioning compressor, driven from the crankshaft pulley via a single six-ribbed belt.

Fuel Injection Pump Belt

The fuel injection pump is driven from the exhaust camshaft of the left-hand cylinder bank, by a single, toothed belt. The fuel injection pump is **NOT** timed to the engine.

For a detailed description of the diesel engine accessory drive belts, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

[Accessory Drive](#) (303-05A Accessory Drive - TDV6 2.7L Diesel, Description and Operation),

[Accessory Drive](#) (303-05A Accessory Drive - TDV6 2.7L Diesel, Description and Operation),

Accessory Drive (303-05A, Description and Operation).

Inspection and Verification

1. Verify the customer concern.
2. Visually inspect for obvious signs of damage and system integrity.

FEAD Belt	Fuel Injection Pump Belt
<ul style="list-style-type: none"> ● Belt condition (cracking/damage/contamination) ● Belt tension ● Function of driven components (seized, etc) ● Pulley alignment 	<ul style="list-style-type: none"> ● Security/correct fitment of cover ● Check for debris inside the cover ● Belt condition (cracking/damage/contamination) ● Belt tension

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart.

Noise Definitions

Description of Noise	Definition/Possible Cause
Squeal	Continuous shriek, most noticeable when the engine is accelerated (usually associated with lack of belt tension, contamination or wet slip)
Chirp	Continuous shriek, most noticeable when the engine is accelerated (usually associated with lack of belt tension, contamination or wet slip)
Whine	Continuous noise, changing frequency with engine speed, generally associated with rotating components (generator, idler, etc)
Rattle	Metallic knocking, often a loose component or tensioner fault
Rumble	Bearing noise

Symptom Chart

CAUTION: The engine should not be run for long periods of time with the FEAD belt removed. Failure to follow this instruction may result in damage to the vehicle.

FEAD Belt

Symptom	Possible Cause	Action
Noise (see definitions above)	<ul style="list-style-type: none"> ● Belt condition ● Belt tension ● Pulleys misaligned ● Driven components 	Check the belt condition. Check the tensioner operation. Check the pulley alignment. Check the driven components for excessive resistance to rotation. Remove FEAD belt and start engine to eliminate from source of noise. Rectify as required
Drive belt does not hold tension	<ul style="list-style-type: none"> ● Belt condition ● Tensioner fault 	Check the belt condition (see visual inspection). Check the tensioner function. Rectify as necessary.

Fuel Injection Pump Belt

Symptom	Possible Cause	Action
Noise (see definitions above)	<ul style="list-style-type: none"> ● Belt condition ● Belt fouling cover ● Tensioner bearing failure ● Fuel injection pump failure 	Check the belt condition. Check the belt cover for indications of fouling (this may indicate a pump misalignment), REFER to: Fuel Injection Pump (303-04A Fuel Charging and Controls - TDV6 2.7L Diesel, Removal and Installation). The belt tensioner must be renewed if the belt is removed, making a check of the bearing impractical. Remove the belt, check the fuel injection pump pulley for security. Check the fuel injection pump for excessive resistance to rotation (excessive resistance in the pump will cause the pulley securing nut to loosen as a design feature). Check for DTCs indicating a pump malfunction and refer to the relevant DTC Index

Symptom	Possible Cause	Action
Loss of drive (with no drive to the fuel injection pump, the engine will not run)	<ul style="list-style-type: none">● Belt broken/stripped teeth● Drive pulleys loose	Investigate the cause of the belt breakage/damage. Check the fuel injection pump for excessive resistance to rotation (excessive resistance in the pump will cause the pulley securing nut to loosen as a design feature). Check for DTCs indicating a pump malfunction and refer to the relevant DTC Index

For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
3. Remove the secondary bulkhead center panel.
For additional information, refer to: [Secondary Bulkhead Center Panel](#) (501-02 Front End Body Panels, Removal and Installation).
4. Remove the cover from the engine wiring harness casing.
 - Release the 7 retaining clips.

5. Remove the engine wiring harness casing.
 - Remove the 4 retaining bolts.

6. Remove the fuel injection pump belt cover.

7. Cut off and discard the fuel injection pump belt.

E130869

8. NOTE: The fuel injection pump is not timed to the engine.

Remove and discard the fuel injection pump belt tensioner.

E125177

Installation

1. CAUTIONS:

 Make sure that the fuel injection pump belt tensioner tang is correctly located to the fuel injection pump belt rear cover. Failure to follow this instruction may result in damage to the engine.

 Make sure that the fuel injection pump belt tensioner locking pin is not removed until the fuel injection pump belt tensioner is fully installed.

• NOTE: Do not remove the fuel injection pump belt tensioner locking pin before installing the new tensioner.

Install the fuel injection pump belt tensioner retaining bolt.

- Locate the tang on the new fuel injection pump belt tensioner into the fuel injection pump rear cover.
- Tighten to 25 Nm.

2.  CAUTION: Make sure that the fuel injection pump belt tensioner tang is correctly located to the fuel injection pump belt rear cover. Failure to follow this instruction may result in damage to the engine.

Install the new fuel injection pump belt.

E125177

E125178

3. Remove and discard the fuel injection pump belt tensioner locking pin.

4. Install the fuel injection pump belt cover.

5. Install the engine wiring harness casing.

6. Install the engine wiring harness cover.

7. Install the secondary bulkhead center panel.
For additional information, refer to: [Secondary Bulkhead Center Panel](#) (501-02 Front End Body Panels, Removal and Installation).
8. Install the engine cover.
For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
9. Connect the battery ground cable.

Accessory Drive - V6 3.0L Petrol - Accessory Drive - Overview

Description and Operation

Overview

The combined crankshaft pulley and torsional vibration damper drives a single, 6-ribbed vee belt. The belt drives all of the engine-mounted accessories such as the generator, the power steering pump, the [A/C \(air conditioning\)](#) compressor and the coolant pump.

The accessory drive belt, which is a maintenance free poly-V type belt, is automatically pre-loaded by the belt tensioner and routed over idlers in order to maintain sufficient adhesion about the drive wheels. This ensures slip-free drive of the accessory components.

The torsional vibration damper incorporates compressed rubber between its inner and outer diameters to absorb vibration and shock loads.

The belt tensioner is calibrated to provide the correct amount of tension to the belt for a given drive system. Unless a spring within the tensioner assembly breaks, or some other mechanical part of the tensioner fails, there is no need to check the tensioner for correct tension.

The accessory drive belt should be inspected at every routine service for excessive wear and damage.

Belt tensioner

The belt tensioner consists of an idler pulley, which is free to rotate on a bearing located at the end of a spring-loaded pivot arm.

The accessory drive belt wear indicators are incorporated on the bottom of the accessory drive belt tensioner. When the indicators are aligned the accessory drive belt requires replacing.

Accessory Drive - V6 3.0L Petrol - Accessory Drive

Diagnosis and Testing

Principles of Operation

For a detailed description of the petrol engine accessory drive belts, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

Inspection and Verification

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical
<ul style="list-style-type: none"> ● FEAD belt ● FEAD belt tension ● FEAD belt tensioner ● FEAD belt pulleys ● Supercharger belt ● Supercharger belt tension ● Supercharger belt tensioner ● Supercharger belt pulley

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart.

Noise Definitions

Description of Noise	Definition/Possible Cause
Squeal	Continuous shriek, most noticeable when the engine is accelerated (usually associated with lack of belt tension, contamination or wet slip)
Chirp	Continuous shriek, most noticeable when the engine is accelerated (usually associated with lack of belt tension, contamination or wet slip)
Whine	Continuous noise, changing frequency with engine speed, generally associated with rotating components (generator, idler, etc)
Rattle	Metallic knocking, often a loose component or tensioner fault
Rumble	Bearing noise

Symptom Chart

Symptom	Possible Cause	Action
FEAD belt noise or squeal	<ul style="list-style-type: none"> ● FEAD belt pulley(s) ● Lubricant or other contamination ● FEAD belt 	Determine where the noise is coming from (refer to the noise definitions above). Check pulley for correct alignment, freedom of rotation or damage. Install new components as required. Check FEAD belt for contamination. If contaminated, install a new belt as required. Check FEAD belt for correct application
FEAD belt does not hold tension	<ul style="list-style-type: none"> ● FEAD belt cracking or damaged ● Tensioner worn or damaged 	Inspect FEAD belt for cracking or damage. Install a new belt as required. Check FEAD belt tensioner for damage and correct operation. Install a new FEAD belt tensioner as required
Supercharger belt noise or squeal	<ul style="list-style-type: none"> ● Supercharger belt pulley(s) ● Lubricant or other contamination ● Supercharger belt 	Determine where the noise is coming from (refer to the noise definitions above). Check pulley for correct alignment, freedom of rotation or damage. Install new components as required. Check supercharger belt for contamination. If contaminated, install a new belt as required. Check supercharger belt for correct application
Supercharger belt does not hold tension	<ul style="list-style-type: none"> ● Supercharger belt cracking or damaged ● Tensioner worn or damaged 	Inspect supercharger belt for cracking or damage. Install a new belt as required. Check supercharger belt tensioner for damage and correct operation. Install a new supercharger belt tensioner as required

Component Tests

FEAD Belt Tensioner

Static

The only checks required for the FEAD belt tensioner are for stick, grab or bind.

1. 1. Remove the drive belt in the area of the tensioner.

2. **2.** Using the correct tool, rotate the tensioner from its relaxed position through its full stroke and back to the relaxed position to make sure there is no stick, grab or bind, and to make sure that there is tension on the tensioner spring.
3. **3.** If the tensioner meets the above criteria, proceed to the dynamic test. If the tensioner does not meet the above criteria install a new tensioner. REFER to:

[Accessory Drive Belt Tensioner](#) (303-05B Accessory Drive - V6 3.0L Petrol, Removal and Installation),
[Accessory Drive Belt Tensioner](#) (303-05C Accessory Drive - V8 4.2L Petrol, Removal and Installation),
[Accessory Drive Belt Tensioner](#) (303-05D Accessory Drive - V8 S/C 4.2L Petrol, Removal and Installation).

Dynamic

The FEAD belt tensioner can be checked dynamically as follows:

4. **4.** With the engine running, observe drive belt tensioner movement, the FEAD belt tensioner should move (respond) when the air conditioning clutch cycles (if equipped), the FEAD belt tensioner should move (respond) when the engine speed is increased rapidly. If the drive belt tensioner movement is erratic without air conditioning clutch cycling or engine acceleration, a pulley or shaft may be bent, or distorted. Excessive drive belt rideout (uneven depth of grooves in the drive belt) can also cause excessive drive belt tensioner movement. Check condition by installing a known good belt. REFER to:

[Accessory Drive Belt](#) (303-05B Accessory Drive - V6 3.0L Petrol, Removal and Installation),

Accessory Drive - 4.2L SC V8 - AJV8 - Accessory Drive - Overview

Description and Operation

Overview

The combined crankshaft pulley and torsional vibration damper drives a single, 6-ribbed primary belt and a double-sided, 8-ribbed secondary belt. The primary belt drives all of the engine-mounted accessories such as the generator, the power steering pump, the [A/C \(air conditioning\)](#) compressor and the coolant pump and the secondary belt drives the supercharger.

The accessory drive belts, which are maintenance free poly-V type belts, are automatically pre-loaded by the belt tensioner and routed over idlers in order to maintain sufficient adhesion about the drive wheels. This ensures slip-free drive of the accessory components.

The torsional vibration damper incorporates compressed rubber between its inner and outer diameters to absorb vibration and shock loads.

The belt tensioner is calibrated to provide the correct amount of tension to the belt for a given drive system. Unless a spring within the tensioner assembly breaks, or some other mechanical part of the tensioner fails, there is no need to check the tensioner for correct tension.

The accessory drive belt should be inspected at every routine service for excessive wear and damage.

Belt Tensioner

The belt tensioner consists of an idler pulley, which is free to rotate on a bearing located at the end of a spring-loaded pivot arm.

The accessory drive belt wear indicators are incorporated on the bottom of the accessory drive belt tensioner. When the indicators are aligned the accessory drive belt requires replacing.

Starting System - TDV6 2.7L Diesel - Starting System - Overview

Description and Operation

Overview

The starter motor is rated as 2.0 kW and is a Denso level 3-sealed unit. It is a P76S type starter motor and is of conventional design with the motor in line and the drive pinion and solenoid mounted above. Each starter motor is of the pre-engaged type and comprises a series wound motor, an overrunning clutch and an integral solenoid. This starter incorporates labyrinth-breathing tubes to help with sealing and drainage.

The starter solenoid is energised by a signal from the [ECM \(engine control module\)](#) when the ignition switch is moved to the crank position. When engine cranking is requested, the [ECM](#) checks that a valid key code has been received before granting the crank request. The power for starter operation is supplied on a substantial single cable connected direct from the battery positive terminal. The cable is connected to the solenoid via a copper threaded stud and secured with a nut.

The starter motor is located on the rear [RH \(right-hand\)](#) side of the engine block and protrudes through an aperture to drive the flywheel via a ring gear. The motor is secured to the cylinder block by 2 bolts and to the ladder frame by four bolts and a support bracket. The bracket provides crucial support for the starter motor and must not be omitted when installing or reinstalling the unit.

Starting System - TDV6 2.7L Diesel - Starting System

Diagnosis and Testing

Principles of Operation

For a detailed description of the starting system, refer to the relevant Description and Operation section in the workshop manual. REFER to:

[Starting System](#) (303-06A Starting System - TDV6 2.7L Diesel, Description and Operation),
[Starting System](#) (303-06A Starting System - TDV6 2.7L Diesel, Description and Operation),
 Starting System (303-06A, Description and Operation),
[Anti-Theft - Passive](#) (419-01B Anti-Theft - Passive, Description and Operation),
[Anti-Theft - Passive](#) (419-01B Anti-Theft - Passive, Description and Operation),
[Anti-Theft - Passive](#) (419-01B Anti-Theft - Passive, Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. Verify the customer concern.
2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Starter Motor ● Battery 	<ul style="list-style-type: none"> ● Battery ● Fuses ● Wiring harness ● Damaged, loose or corroded connectors ● Starter relay ● Engine Control Module (ECM)

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the concern is not visually evident, verify the symptom and refer to the symptom chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
The engine does not crank (starter motor does not turn)	<ul style="list-style-type: none"> ● Gear selector not in P or N position ● Battery ● Harness/Connectors ● Starter motor ● Starter relay ● Start switch ● Transmission control module (TCM) ● Engine control module (ECM) ● Engine seized 	Make sure the gear selector is in the P or N position. Check the battery is in fully charged and serviceable condition. Check the starter motor and harness. Check for related DTCs and refer to the relevant DTC Index
The engine does not crank (starter motor does turn)	<ul style="list-style-type: none"> ● Starter motor installation ● Starter motor ● Ring gear 	Check the starter motor installation (fasteners tight, starter motor square to engine, etc). Check the ring gear teeth for damage, foreign objects, etc.
Engine cranks too slowly	<ul style="list-style-type: none"> ● Battery ● Harness/Connectors ● Starter motor ● Engine oil incorrect grade 	Check the battery is in fully charged and serviceable condition. Refer to the electrical circuit diagrams and test the starter motor and starter motor circuits
Engine cranks too fast	<ul style="list-style-type: none"> ● Low engine compression 	Check the engine compressions. REFER to: Engine - TDV6 2.7L Diesel (303-00 Engine System - General Information, Diagnosis and Testing).
Excessive starter motor noise	<ul style="list-style-type: none"> ● Starter motor ● Starter motor installation/casing ● Ring gear 	Check the starter motor installation (fasteners tight, motor square to engine, etc). Check the starter motor casing condition. Check the ring gear teeth for damage, foreign objects, etc.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00. Failure to follow this instruction may result in damage to the vehicle.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to 3 decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, the fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B100951	Ignition Authorisation	<ul style="list-style-type: none"> Faulty instrument cluster Target SID re-synchronisation error following programming CAN fault 	Check ignition, power and ground supplies to CJB and instrument cluster. Re-synchronize ID by re-configuring the instrument cluster as a new module. Check CAN communications between instrument cluster and tester

Starting System - TDV6 2.7L Diesel - Starter Motor

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).

3.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

4. Make sure the alignment mark, on the steering gear pinion seal protection cover, is central to the steering gear pinion casting.

E42703

5. Remove the steering gear shaft pinch bolt.

VUJ0002958

6. Detach the steering gear.

E31036

7. Secure the steering gear.

E 31035

8. Disconnect the power steering control valve actuator electrical connector.

E 49770

9. Remove the starter motor retaining bracket.

E 51240

10. Detach the starter motor solenoid harness.

E 50718

11. Detach the starter motor cable.

E 50719

12. Remove the starter motor.

Installation

1. To install, reverse the removal procedure.

- Tighten to 48 Nm.

2. Tighten to 10 Nm.

3. Tighten to 7 Nm.

4. Tighten to 23 Nm.

5. Tighten to 100 Nm.

6. Tighten to 35 Nm.

7. Make sure the alignment mark, on the steering gear pinion seal protection cover, is central to the steering gear pinion casting.

Starting System - V6 3.0L Petrol -

Description	Nm	lb-ft	lb-in

Solenoid terminal integral connector nut	6	-	53

Starting System - V6 3.0L Petrol - Starting System - Component Location

Description and Operation

Component Location

E93235

Starting System - V6 3.0L Petrol - Starting System - Overview

Description and Operation

Overview

The starter motor is rated as a 1.8 kW and is a Denso level 3-sealed unit. It is an RA type starter motor, which is of the offset design with the solenoid being directly behind the pinion to give a more positive engagement to the ring gear. The motor is geared directly to the pinion. Each starter motor is of the pre-engaged type and comprises a series wound motor and an overrunning clutch. This starter incorporates labyrinth-breathing tubes to help with sealing and drainage.

The starter solenoid is energised by a signal from the [ECM \(engine control module\)](#) when the ignition switch is moved to the crank position. When engine cranking is requested, the [ECM](#) checks that a valid key code has been received before granting the crank request.

The power for starter operation is supplied on a substantial single cable connected direct from the battery positive terminal. The cable is connected to the solenoid via a copper threaded stud with an anti-rotational device and secured with a nut.

The starter motor is located on the rear [RH \(right-hand\)](#) side of the engine block. The motor is secured to the block and protrudes through an aperture to drive the flywheel via a ring gear.

Starting System - V6 3.0L Petrol - Starting System

Diagnosis and Testing

Principles of Operation

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Starter Motor ● Battery 	<ul style="list-style-type: none"> ● Battery ● Fuses ● Wiring harness ● Damaged, loose or corroded connectors ● Starter relay ● Engine Control Module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the concern is not visually evident, verify the symptom and refer to the symptom chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
The engine does not crank (starter motor does not turn)	<ul style="list-style-type: none"> ● Gear selector not in P or N position ● Battery ● Harness/Connectors ● Starter motor ● Starter relay ● Start switch ● Transmission control module (TCM) ● Engine control module (ECM) ● Engine seized 	Make sure the gear selector is in the P or N position. Check the battery is in fully charged and serviceable condition. Check the starter motor and harness. Check for related DTCs and refer to the relevant DTC Index
The engine does not crank (starter motor does turn)	<ul style="list-style-type: none"> ● Starter motor installation ● Starter motor ● Ring gear 	Check the starter motor installation (fasteners tight, starter motor square to engine, etc). Check the ring gear teeth for damage, foreign objects, etc.
Engine cranks too slowly	<ul style="list-style-type: none"> ● Battery ● Harness/Connectors ● Starter motor ● Engine oil incorrect grade 	Check the battery is in fully charged and serviceable condition. Refer to the electrical circuit diagrams and test the starter motor and starter motor circuits
Engine cranks too fast	<ul style="list-style-type: none"> ● Low engine compression 	Check the engine compressions. REFER to: Engine - V8 4.2L Petrol/V8 S/C 4.2L Petrol/3.0L NA V6 - AJ27 (303-00 Engine System - General Information, Diagnosis and Testing).
Excessive starter motor noise	<ul style="list-style-type: none"> ● Starter motor ● Starter motor installation/casing ● Ring gear 	Check the starter motor installation (fasteners tight, motor square to engine, etc). Check the starter motor casing condition. Check the ring gear teeth for damage, foreign objects, etc.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00. Failure to follow this instruction may result in damage to the vehicle.

- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).

NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to 3 decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

NOTE: If DTCs are recorded and, after performing the pinpoint tests, the fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Starting System - V6 3.0L Petrol - Starter Motor

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Raise and support the vehicle.
3. Remove the air deflector.
For additional information, refer to: [Air Deflector](#) (501-02 Front End Body Panels, Removal and Installation).
4. Disconnect the engine ground cable.

5. Remove the starter motor positive cable cover.

6. Release the starter motor positive cable.

7. Remove the steering gear shaft pinch bolt.

8. Release the steering gear.

E31036

9. Remove the starter motor.

- Remove the starter motor retaining bolts.

VUJ0000841

Installation

1. To install, reverse the removal procedure.

- Tighten to 25 Nm.

VUJ0000841

2. Tighten to 100 Nm.

E31036

3. Tighten to 35 Nm.

VUJ0005119

4. Tighten to 13 Nm.

E30140

5. Tighten to 7 Nm.

E30141

Starting System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Starting System - Overview

Description and Operation

Overview

The starter motor is rated as a 1.8 kW and is a Denso level 3-sealed unit. It is an RA type starter motor, which is of the offset design with the solenoid being directly behind the pinion to give a more positive engagement to the ring gear. The motor is geared directly to the pinion. Each starter motor is of the pre-engaged type and comprises a series wound motor and an overrunning clutch. This starter incorporates labyrinth-breathing tubes to help with sealing and drainage.

The starter solenoid is energised by a signal from the [ECM \(engine control module\)](#) when the ignition switch is moved to the crank position. When engine cranking is requested, the [ECM](#) checks that a valid key code has been received before granting the crank request.

The power for starter operation is supplied on a substantial single cable connected direct from the battery positive terminal. The cable is connected to the solenoid via a copper threaded stud with an anti-rotational device and secured with a nut.

The starter motor is located on the rear [RH \(right-hand\)](#) side of the engine block. The motor is secured to the block and protrudes through an aperture to drive the flywheel via a ring gear.

Starting System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Starting System

Diagnosis and Testing

Principles of Operation

For a detailed description of the starting system, refer to the relevant Description and Operation section in the workshop manual. REFER to:

Engine Ignition - V6 3.0L Petrol - Engine Ignition - Overview

Description and Operation

OVERVIEW

The 3.0L V6 engine ignition system has a single iridium tipped spark plug per cylinder, with each spark plug powered by an on-plug ignition coil. The ignition coils are directly driven by the ECM.

Power for the ignition coils is supplied from the main relay and a fuse in the BJB. A capacitor is connected in parallel with the power supplies to the ignition coils to suppress RFI (radio frequency interference).

9	RJB (rear junction box)

System Operation

Engine Ignition

Each ignition coil contains a power stage to switch the current in the primary circuit. The [ECM](#) controls the switching with a signal to the power stage. The [ECM](#) monitors operation of the ignition coils using a feedback signal from each of the power stages. If a fault is detected the [ECM](#) stores an appropriate fault code.

Power for the ignition coils is supplied from the main relay and a fuse in the [BJB](#). A capacitor is connected in parallel with the power supplies to the ignition coils to suppress RFI (radio frequency interference).

The [ECM](#) varies the dwell time of the ignition coils depending on battery voltage and engine speed, to ensure a constant energy level is produced in the secondary coil each time the power stage is switched. This ensures a good spark is always produced by the spark plug without excessive primary current flow, thus avoiding overheating or damage to the ignition coils.

The [ECM](#) calculates the ignition timing for individual cylinders from:

- Engine speed
- Camshaft position
- Engine load
- Engine temperature
- The knock control function
- The shift control function
- The idle speed control function.

Component Description

Ignition Coils

The engine is fitted with eight plug-top coils that are controlled directly by the [ECM](#). This means that the [ECM](#), at the point where sufficient charge has built up, switches the primary circuit of each coil and a spark is produced in the spark plug. The positive supply to the coil is fed from a common fuse. Each coil contains a power stage to trigger the primary current. The [ECM](#) sends a signal to each of the coils power stage to trigger the power stage switching. Each bank has a feedback signal that is connected to each power stage. If the coil power stage has a failure the feedback signal is not sent, causing the [ECM](#) to store a fault code appropriate to the failure.

The [ECM](#) calculates the dwell time depending on battery voltage and engine speed to ensure constant secondary energy. This ensures sufficient secondary (spark) energy is always available, without excessive primary current flow thus avoiding overheating or damage to the coils.

The individual cylinder spark timing is calculated from a variety of inputs:

- Engine speed and load
- Engine temperature
- Knock control
- Transmission shift control
- Idle speed control.

Engine Ignition - V6 3.0L Petrol - Engine Ignition

Diagnosis and Testing

Principles of Operation

For a detailed description of the ignition system, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after the pinpoint tests have been carried out, the fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Engine Ignition - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Engine Ignition - Overview

Description and Operation

OVERVIEW

The 4.2L V8 Normally Aspirated and Supercharged engine ignition systems have a single iridium tipped spark plug per cylinder, with each spark plug powered by an on-plug ignition coil. The ignition coils are directly driven by the [BJB \(battery junction box\)](#).

Power for the ignition coils is supplied from the main relay and a fuse in the [BJB](#). A capacitor is connected in parallel with the power supplies to the ignition coils to suppress RFI (radio frequency interference).

Each ignition coil contains a power stage to switch the current in the primary circuit. The [ECM \(engine control module\)](#) controls the switching with a signal to the power stage. The [ECM](#) monitors operation of the ignition coils using a feedback signal from each of the power stages. If a fault is detected the [ECM](#) stores an appropriate fault code.

The [ECM](#) varies the dwell time of the ignition coils depending on battery voltage and engine speed, to ensure a constant energy level is produced in the secondary coil each time the power stage is switched. This ensures a good spark is always produced by the spark plug without excessive primary current flow, thus avoiding overheating or damage to the ignition coils.

The [ECM](#) calculates the ignition timing for individual cylinders from:

- Engine speed
- Camshaft position
- Engine load
- Engine temperature
- The knock control function
- On automatic transmission models, the shift control function
- The idle speed control function.

Power for the ignition coils is supplied from the main relay and a fuse in the [BJB](#). A capacitor is connected in parallel with the power supplies to the ignition coils to suppress RFI (radio frequency interference).

The [ECM](#) varies the dwell time of the ignition coils depending on battery voltage and engine speed, to ensure a constant energy level is produced in the secondary coil each time the power stage is switched. This ensures a good spark is always produced by the spark plug without excessive primary current flow, thus avoiding overheating or damage to the ignition coils.

The [ECM](#) calculates the ignition timing for individual cylinders from:

- Engine speed
- Camshaft position
- Engine load
- Engine temperature
- The knock control function
- The shift control function
- The idle speed control function.

Component Description

Ignition Coils

The engine is fitted with eight plug-top coils that are controlled directly by the [ECM](#). This means that the [ECM](#), at the point where sufficient charge has built up, switches the primary circuit of each coil and a spark is produced in the spark plug. The positive supply to the coil is fed from a common fuse. Each coil contains a power stage to trigger the primary current. The [ECM](#) sends a signal to each of the coils power stage to trigger the power stage switching. Each bank has a feedback signal that is connected to each power stage. If the coil power stage has a failure the feedback signal is not sent, causing the [ECM](#) to store a fault code appropriate to the failure.

The [ECM](#) calculates the dwell time depending on battery voltage and engine speed to ensure constant secondary energy. This ensures sufficient secondary (spark) energy is always available, without excessive primary current flow thus avoiding overheating or damage to the coils.

The individual cylinder spark timing is calculated from a variety of inputs:

- Engine speed and load
- Engine temperature
- Knock control
- Transmission shift control
- Idle speed control.

Glow Plug System - Glow Plug System - Overview

Description and Operation

OVERVIEW

The glow plug system has a glow plug installed in the inlet side of each cylinder. The glow plugs heat the combustion chambers before and during cranking, to aid cold starting, and after the engine starts to reduce emissions and engine noise when idling with a cold engine.

The glow plugs are connected for each bank by a common harness which is connected into the main engine harness. The harness for each bank connects into a connector block which attaches to each of the glow plugs for that bank. The glow plugs are connected directly to the glow plug module which is controlled by glow plug software contained within the [ECM \(engine control module\)](#).

Each glow plug is a tubular heating element which contains a spiral filament encased in magnesium oxide powder. At the tip of the tubular heating element is the heater coil. Behind the heater coil, and connected in series, is a control coil. The control coil regulates the current to the heater coil to safeguard against overheating.

System Operation

System Operation

There are three phases of glow plug heating:

- Pre heating
- Crank heating
- Post heating

The **ECM (engine control module)** determines the heating times from the **ECT (engine coolant temperature)**. The lower the **ECT**, the longer the heating times.

When the ignition is switched to power mode 9 (engine crank), the **ECM** calculates any required heating times and, if heating is required, energizes the glow plug relay in the **BJB (battery junction box)**. The glow plug relay supplies an ignition power supply to the glow plug module. The glow plug module is controlled by the **ECM** which determines the pre-heat time required. The module then supplies power to each of the glow plugs for the required time.

When pre-heating is required, the **ECM** also sends a message to the instrument cluster, on the high speed **CAN**, to request illumination of the glow plug indicator. The glow plug indicator remains illuminated for the duration of the pre heating phase, or until the ignition is switched to crank, whichever occurs first. If required, the **ECM** keeps the glow plug module energized during cranking and for the duration of any post heating phase.

The **ECM** monitors the drive circuit of the glow plug module, via a direct diagnostic connection with the module, for plausibility of operation, continuity, and short and open circuits. If a fault is detected, the glow plug module passes the fault information to the **ECM**, which stores a related fault code and permanently illuminates the glow plug indicator while the ignition is in power mode 9.

Pre Heating

Pre-heat is the length of time the glow plugs operate prior to engine cranking. The **ECM** controls the pre-heat time based on **ECT** sensor output and battery voltage. If the **ECT** sensor fails, the **ECM** will use the **IAT (intake air temperature)** sensor value as a default value. The pre-heat duration is extended if the coolant temperature is low and the battery is not fully charged.

The **ECM** receives the corresponding temperature signal from the **ECT** sensor.

The pre heating period is dependent on the temperature signal (low temperature = longer pre heating period).

The driver is informed that pre heating is in operation by the glow plug indicator light in the instrument cluster coming on. The pre heating times become longer as the coolant temperature falls.

The [BARO \(barometric pressure\)](#) also has an influence on activation and deactivation of the glow plugs in the event of large altitude differences.

Crank Heating

Crank heating is carried out at every start where the coolant temperature is below the predefined threshold of 20° C. Crank heating begins if the engine speed exceeds 42 rpm for longer than 50ms, or the starter is active for longer than 4 sec. If the coolant temperature sensor is defective, a default temperature of 0° C is used.

Post Heating

Post heat is the length of time the glow plugs operate after the engine starts. The [ECM](#) controls the post heating time based on [ECT](#) sensor output. The post heat phase reduces engine noise, improves idle quality and reduces hydrocarbon emissions.

Preheating is followed by the post heating phase once the engine has started. The post heating phase depends upon how the vehicle is driven.

In addition to [ECT](#), [BARO](#) and engine speed, the injected fuel quantity is significant in this context. For example, if the injected fuel quantity is 70 mg per piston stroke and the coolant temperature is below 20 °C, post heating is performed at engine speeds between 1100 and 3500 rpm.

In the case of greater injection quantities and considerably lower engine temperatures, the post heating phase is also activated depending on the engine speed. At 14 mg per piston stroke and an [ECT](#) of below 0 °C, for example, post heating is performed at engine speeds between 1100 and 1500 rpm.

Component Description

Glow Plug

The ceramic sheathed element glow plugs are made from a heat-resistant, electrically conductive ceramic material. The ceramic sheathed-element glow plugs outer layer is heated directly and is self regulating. The self regulation allows the resistance of the sheathed element to automatically increase as the heat increases preventing the glow plug from overheating. In addition, during the heating process and under the control of the glow plug relay, the glow plugs can be operated above their nominal voltages. This permits heat-up speeds of 1000°C per second. The sheathed-element glow plugs reach a maximum glow temperature of 1300°C and can hold a temperature of 1150°C for several minutes after the first-start glow or at intervening times.

The glow plug is a tubular heating element that protrudes into the combustion chamber of the engine. The heating element contains a spiral filament encased in magnesium oxide powder. At the tip of the tubular heating element is the heater coil. Behind the heater coil is a control coil. The control coil is connected in series and regulates the heater coil to ensure that it does not overheat.

Each cylinder bank has a separate harness connecting the three glow plugs. The harness connects into the engine wiring harness and each harness has a connector block which attaches to each of the glow plugs for that bank.

The glow plug module receives a battery voltage feed via a 250A megafuse in the [BJB](#) and a 100A midi-fuse in the [EJB \(engine junction box\)](#). Operation of the glow plug module is controlled by the [ECM](#), which also controls the illumination of the glow plug indicator in the instrument cluster.

The system has been designed as a low-voltage glow system. At 7 volts, the nominal voltage of the sheathed-element glow plugs is significantly lower than the 12 volts of the main electrical circuit. The electronic glow plug module matches the voltage to the sheathed-element glow plugs and controls their glow temperature precisely to the specific requirements of the engine. This produces the optimum glow temperature even when the main circuit voltage is interrupted during engine starting. The lower power consumption of the ceramic glow plugs and their time-staggered activation reduce to a minimum the peak load on the main circuit during the cold start and immediate post-start periods.

In the event of glow plug failure, the engine may be difficult to start and excessive smoke emissions may be observed after starting.

Glow Plug Module

The glow plug module is located in the [RH \(right-hand\)](#) side of the engine compartment. The module is attached to the power steering reservoir bracket with a bolt and nut.

Two connectors are used on the module. One connector receives the power supplies from the battery via the [BJB](#) and [EJB](#) and also provides for the connections to/from the [ECM](#). The second connector supplies the outputs to the glow plugs.

Engine Emission Control - TDV6 2.7L Diesel - Engine Emission Control - Overview

Description and Operation

OVERVIEW

The combined [EGR \(exhaust gas recirculation\)](#) modulator and cooler is located under each cylinder bank, between the exhaust manifold and the cylinder head. The cooler side of the [EGR](#) is connected to the vehicle cooling system, via hoses. The inlet exhaust side is connected directly into the exhaust manifolds on each side. A flow regulating, wax thermostat is fitted to the coolant outlet of the [EGR](#) cooler. The purpose of the thermostat is to promote faster engine warm-up, improve cabin heater performance and assist the emissions to comply with the requirements of EU4 regulations. The exhaust gas passes through the cooler and is expelled via the actuator and a metal pipe into the throttle housing. The [EGR](#) modulator is a solenoid operated valve which is controlled by the [ECM \(engine control module\)](#). The [ECM](#) uses the [EGR](#) modulator to control the amount of exhaust gas being recirculated in order to reduce exhaust emissions and combustion noise. [EGR](#) is enabled when the engine is at normal operating temperature and under cruising conditions.

The crankcase ventilation system ensures that all gasses emitted from the crankcase during engine running are separated from any oil particles. Crankcase gasses are drawn into the oil separator unit from the crankcase and the cylinder head covers (both banks) where the gas and oil are separated. The gas is returned to the inlet side of the air induction system prior to the turbo charger. The oil is drained down to the sump via an oil return valve locate at the rear of the cylinder block.

Operation and Component Description

Description and Operation

System Operation

The [EGR \(exhaust gas recirculation\)](#) system comprises: [EGR](#) modulator x 2 [EGR](#) cooler x 2 Associated connecting pipes The combined [EGR](#) modulator and cooler is located between the V of the cylinder banks. The cooler side of the [EGR](#) is connected to the vehicle cooling system, via hoses. The inlet exhaust side is connected to the exhaust manifolds on each side via a metal pipe. The exhaust gas passes through the cooler and is expelled via the actuator and a metal pipe into the throttle housing. The [EGR](#) modulator is a solenoid operated valve which is controlled by the [ECM \(engine control module\)](#). The [ECM](#) uses the [EGR](#) modulator to control the amount of exhaust gas being recirculated in order to reduce exhaust emissions and combustion noise. The [EGR](#) is enabled when the engine is at normal operating temperature and under cruising conditions.

The crankcase ventilation system on the engine ensures that all gasses emitted from the crankcase during engine running are separated from any oil particles.

Component Description

EGR Valve and Cooler

E99983

ItemDescription

- | | |
|---|-------------------------------|
| 1 | EGR modulator |
| 2 | EGR cooler |

The combined [EGR](#) modulator and cooler is located under each cylinder bank, between the exhaust manifold and the cylinder head. The cooler side of the [EGR](#) is connected to the vehicle cooling system, via hoses. The inlet exhaust side is connected directly into the exhaust manifolds on each side. The exhaust gas passes through the cooler and is expelled via the actuator and a metal pipe into the throttle housing. The [EGR](#) modulator is a solenoid operated valve which is controlled by the [ECM](#). The [ECM](#) uses the [EGR](#) modulator to control the amount of exhaust gas being recirculated in order to reduce exhaust emissions and combustion noise. The [EGR](#) is enabled when the engine is at normal operating temperature and under cruising conditions.

A flow regulating, wax thermostat is fitted to the coolant outlet of the [EGR](#) cooler. The purpose of the thermostat is to promote faster engine warm-up, improve cabin heater performance and assist the emissions to comply with the requirements of EU4 regulations. The thermostat is closed when cold, starts to open at 75°C (167°F) and is fully open at normal operating temperatures. The thermostat has a small bleed hole which allows a small amount of leakage when cold.

The [EGR](#) modulator receives a 12V supply from the main relay. The ground for the solenoid is via the [ECM](#) and is controlled using a [PWM \(pulse width modulation\)](#) signal. The [PWM](#) duty signal of the solenoid ground is varied to determine the precise amount of exhaust gas delivered to the cylinders.

The modulators are operated through their full range at each engine start-up, to clear any carbon deposits that may have built up whilst the engine was running

In the event of a failure of the [EGR](#) modulator, the [EGR](#) function will become inoperative. The [ECM](#) can monitor the [EGR](#) modulator solenoid for short circuits and store fault codes in the event of failure. The modulator can also be activated for testing using the recommended Jaguar diagnostic tool.

Crankcase Ventilation

Crankcase gasses are drawn into the oil separator unit from the crankcase and the cylinder head covers (both banks) where the gas and oil are separated. The gas is returned to the intake side of the air induction system prior to the turbo charger. The oil is drained down to the sump via an oil return valve located at the rear of the cylinder block.

Engine Emission Control - TDV6 2.7L Diesel - Engine Emission Control

Diagnosis and Testing

Principles of Operation

For a detailed description of the diesel engine emission control system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (303-08A Engine Emission Control - TDV6 2.7L Diesel)

[Engine Emission Control](#) (Description and Operation),

[Engine Emission Control](#) (Description and Operation),

[Engine Emission Control](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of mechanical or electrical damage.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● EGR valve ● EGR pipes/hoses ● Vacuum system ● Engine breather system 	<ul style="list-style-type: none"> ● Wiring harness ● Electrical connector(s) ● Fuses(s)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Poor performance, excessive smoke emission	<ul style="list-style-type: none"> ● Incorrect EGR flow 	Check EGR valve for correct operation. Check for related DTCs and refer to the relevant DTC Index
Excessive engine blow-by/crankcase pressure	<ul style="list-style-type: none"> ● Engine breather system blocked/restricted ● Excessive engine wear 	Check engine breather system for blockage/restriction. Check for excessive engine wear. REFER to: Engine - TDV6 2.7L Diesel (303-00 Engine System - General Information, Diagnosis and Testing).

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: Inspect connectors for signs of water ingress, and pins for damage and/or corrosion.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
P040121	Exhaust Gas Recirculation Flow Insufficient Detected	<ul style="list-style-type: none"> ● EGR control deviation below minimum threshold ● Engine cooling system fault ● EGR valve control system fault 	<p>• NOTE: This DTC may log if the engine temperature is more than 98°C and the ambient temperature is between 5 - 15°C.</p> <p>Carry out PWM test on EGR control valve. Set ignition status to 'ON', engine 'OFF'. Check and record 'EGR valve position bank 0' and 'EGR valve position bank 1' datalogger signals, and command 'EGR valve 0 command' and 'EGR valve 1 command' to 100% then 0%. Value of the signal should be approximately 95% maximum and 5% minimum, If PWM test is passed check engine cooling system functions correctly. Check correct thermostat is installed. If not, suspect the EGR actuators, check and install new actuators as required</p>

Engine Emission Control - TDV6 2.7L Diesel - Crankcase Vent Oil Separator

Removal and Installation

Removal

1. Remove the engine cover.
For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
2. Remove the secondary bulkhead center panel.
For additional information, refer to: [Secondary Bulkhead Center Panel](#) (501-02 Front End Body Panels, Removal and Installation).
3. Remove the cover from the engine wiring harness casing.

4. Remove the engine wiring harness casing.

5. Disconnect the port deactivation vacuum hose.

6. Disconnect the crankcase vent hoses.

7. CAUTIONS:

Discard the seals.

Make sure that all openings are sealed.

Release and remove the crankcase vent oil separator.

Installation

1. CAUTION: Install the new seals.

• NOTE: Make sure that all the component mating faces are clean.

To install, reverse the removal procedure.

Engine Emission Control - TDV6 2.7L Diesel - Exhaust Gas Recirculation (EGR) Valve Outlet Tube

Removal and Installation

Removal

1. Remove the engine cover.

For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel \(501-05 Interior Trim and Ornamentation, Removal and Installation\)](#).

2. **NOTE:** Right-hand shown, left-hand similar.

Detach the exhaust gas recirculation (EGR) valve outlet tube.

- Remove and discard the clamp.

3. **NOTE:** Right-hand shown, left-hand similar.

Detach the EGR valve outlet tube.

- Release the engine wiring harness.
- Remove the Torx screw.

4. **NOTE:** Right-hand shown, left-hand similar.

- **NOTE:** Discard the gasket.

Remove the EGR valve outlet tube.

- Remove the 2 bolts.

Installation

1. **NOTE:** Right-hand shown, left-hand similar.

Loosely install the EGR valve outlet tube.

- Install a new clamp.
- Do not fully close the retaining clamp at this stage.

2. NOTE: Right-hand shown, left-hand similar.

Loosely install the EGR valve outlet tube bolts.

- Install a new gasket.

E51802

3. NOTE: Right-hand shown, left-hand similar.

Loosely install the bolt.

E51038

4. NOTE: Right-hand shown, left-hand similar.

Fully close the EGR valve outlet tube retaining clamp.

E51277

5. NOTE: Right-hand shown, left-hand similar.

Tighten to 10 Nm.

E51802

6. NOTE: Right-hand shown, left-hand similar.

Tighten to 5 Nm.

E51038

7. Install the engine cover.

Engine Emission Control - TDV6 2.7L Diesel - Exhaust Gas Recirculation (EGR) Valve LH

Removal and Installation

Removal

 **WARNING:** Since injury such as scalding could be caused by escaping steam or coolant, make sure the vehicle cooling system is cool prior to carrying out this procedure.

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the exhaust gas recirculation (EGR) valve outlet tube.
For additional information, refer to: [Exhaust Gas Recirculation \(EGR\) Valve Outlet Tube](#) (303-08A Engine Emission Control - TDV6 2.7L Diesel, Removal and Installation).
3. Reposition the fuel filter and support bracket.

4. Disconnect the EGR valve electrical connector.

5. Clamp the coolant hoses in the locations shown to minimise coolant loss.

6. Disconnect the coolant hose from the EGR valve.

7. Detach the coolant hose.

8. Remove the EGR valve retaining bolt and coolant hose bracket.

- Displace the catalytic converter heatshield downwards to access the bolt.

9. Disconnect the EGR valve inlet tube.

- Remove and discard the clamp.

10. Release the EGR valve.

11. Remove the EGR valve.

- Disconnect the coolant hose.

Installation

1. Install the EGR valve.

- Connect the coolant hose.

2. Loosely install the EGR valve.

3. Install the bracket.

- Displace the catalytic converter heatshield downwards to access the bolt.

4. Connect the EGR valve inlet tube.

- Install a new clamp.

5. Secure the EGR valve.

- Tighten to 10 Nm.

6. Attach the coolant hose.

- Tighten to 10 Nm.

7. Connect the coolant hose to the EGR valve.

8. Connect the EGR valve electrical connector.

9. Secure the fuel filter and support bracket.

- Tighten to 27 Nm.

10. Install the EGR valve outlet tube.

For additional information, refer to: [Exhaust Gas Recirculation \(EGR\) Valve Outlet Tube](#) (303-08A Engine Emission Control - TDV6 2.7L Diesel, Removal and Installation).

11.  **CAUTION:** Anti-freeze concentration must be maintained at 50%.

Fill the cooling system to the upper level mark of the coolant expansion tank.

- Remove the coolant expansion tank bleed screw.
- When coolant runs from the expansion tank bleed point bubble-free, tighten the bleed screw.
- Tighten to 3 Nm.

12. Connect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

13. Start and run the engine.

- Increase engine speed to 2000rpm and cycle between this and idle for 60 seconds.
- Remove the coolant expansion tank cap.

14. Check and top up the cooling system as required.

Engine Emission Control - TDV6 2.7L Diesel - Exhaust Gas Recirculation (EGR) Valve RH

Removal and Installation

Removal

 **WARNING:** Since injury such as scalding could be caused by escaping steam or coolant, make sure the vehicle cooling system is cool prior to carrying out this procedure.

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the exhaust gas recirculation (EGR) valve outlet tube.
For additional information, refer to: [Exhaust Gas Recirculation \(EGR\) Valve Outlet Tube](#) (303-08A Engine Emission Control - TDV6 2.7L Diesel, Removal and Installation).
3. Remove the secondary bulkhead RH panel.
For additional information, refer to: [Secondary Bulkhead Panel RH - V8 4.2L Petrol/V8 S/C 4.2L Petrol/V6 3.0L Petrol/TDV6 2.7L Diesel](#) (501-02 Front End Body Panels, Removal and Installation).
4. Reposition the engine junction box (EJB).
 - Remove the two bolts.
 - Remove the nut.

5. Disconnect the EGR valve electrical connector.

6. Clamp the coolant hoses in the locations shown to minimise coolant loss.

E139452

7. Disconnect the coolant hose from the EGR valve.

E51800

8. Disconnect the EGR valve inlet tube.

- Remove and discard the clamp.

E 51804

9. Release the EGR valve.

E 52868

10. Remove the EGR valve.

- Disconnect the coolant hose.

Installation

1. Install the EGR valve.

- Connect the coolant hose.

2. Loosely install the EGR valve.

3. Connect the EGR valve inlet tube.

- Install a new clamp.

4. Secure the EGR valve.

- Tighten to 10 Nm.

5. Connect the coolant hose to the EGR valve.

6. Remove the coolant hose clamps.

7. Connect the EGR valve electrical connector.

8. Secure the EJB.

- Tighten to 10 Nm.

9. Install the secondary bulkhead RH panel.

For additional information, refer to: [Secondary Bulkhead Panel RH - V8 4.2L Petrol/V8 S/C 4.2L Petrol/V6 3.0L Petrol/TDV6 2.7L Diesel](#) (501-02 Front End Body Panels, Removal and Installation).

10. Install the EGR valve outlet tube.

For additional information, refer to: [Exhaust Gas Recirculation \(EGR\) Valve Outlet Tube](#) (303-08A Engine Emission Control - TDV6 2.7L Diesel,

Removal and Installation).

11.  CAUTION: Anti-freeze concentration must be maintained at 50%.

Fill the cooling system to the upper level mark of the coolant expansion tank.

- Remove the coolant expansion tank bleed screw.
- When coolant runs from the expansion tank bleed point bubble-free, tighten the bleed screw.
- Tighten to 3 Nm.

12. Connect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

13. Start and run the engine.

- Remove the coolant expansion tank cap.
- Increase engine speed to 2000rpm and cycle between this and idle for 60 seconds.

14.  CAUTION: Anti-freeze concentration must be maintained at 50%.

Check and top up the cooling system as required.

Engine Emission Control - V6 3.0L Petrol - Engine Emission Control - Overview

Description and Operation

OVERVIEW

The engine emission control system on the 3.0L engine comprise:

- Crankcase ventilation system
- [AIR \(secondary air injection\)](#) system

The crankcase ventilation system consists of two hoses, connected between the left-hand valve cover and the intake manifold and the right-hand valve cover and the air cleaner outlet pipe and a [PCV \(positive crankcase ventilation\)](#) valve located on the top on the [LH \(left-hand\)](#) engine cam cover. The [PCV](#) system recycles crankcase gases back through the engine where they mix with incoming air/fuel charge and help to reduce hydrocarbon emissions.

The [AIR](#) system comprises the following components:

- [AIR](#) pump
- [AIR](#) switching valve
- [AIR](#) control valve
- [AIR](#) vacuum reservoir
- [AIR](#) pump relay
- [AIR](#) pressure sensor (North American specification vehicles only)

Engine Emission Control - V6 3.0L Petrol - Engine Emission Control - System Operation and Component Description

Description and Operation

System Operation

CRANKCASE VENTILATION SYSTEM

The crank system recycles crankcase gases back through the engine where they mix with incoming air/fuel charge and help to reduce hydrocarbon emissions. The [PCV \(positive crankcase ventilation\)](#) system consists of two hoses, connected between the left-hand valve cover and the intake manifold and the right-hand valve cover and the air cleaner outlet pipe. The [LH \(left-hand\)](#) hose has a [PCV](#) valve at the engine cover end.

The [PCV](#) valve regulates the amount of ventilation air and crankcase gas supplied to the intake manifold and also prevents backfiring into the crankcase.

SECONDARY AIR INJECTION SYSTEM

The [AIR \(secondary air injection\)](#) pump is used to provide a supply of air into the exhaust manifolds during the cold start period of the engine. The [AIR](#) cycle lasts for up to 65 seconds. The hot unburnt fuel particles leaving the combustion chamber mix with the air injected into the exhaust manifolds and immediately combust.

This subsequent combustion of the unburnt and partially burnt carbon monoxide (CO)[CO \(carbon monoxide\)](#) and hydrocarbon (HC)[HC \(hydrocarbon\)](#) particles help to reduce the emission of these pollutants from the exhaust system. The additional heat generated in the exhaust manifold also provides rapid heating of the exhaust system catalytic converters. The additional oxygen which is delivered to the catalytic converters also generates an exothermic reaction which causes the catalytic converters to reach their optimum operating temperature and 'light off' quickly.

The catalytic converters only start to provide effective treatment of emission pollutants when they reach an operating temperature of approximately 250°C (482°F) and need to be between temperatures of 400°C (752°F) and 800°C (1472°F) for optimum efficiency. Consequently, the heat produced by the [AIR](#) 'afterburning' reduces the time delay before the catalysts reach an efficient operating temperature.

Component Description

POSITIVE CRANKCASE VENTILATION VALVE

The [PCV](#) valve is a spring loaded valve that opens when the engine is under full load. Once open the valve allows crankcase gasses to flow to the intake manifold. The [PCV](#) valve prevents reverse flow into the crankcase.

SECONDARY AIR INJECTION PUMP

E62274

The [AIR](#) pump is fitted on rubber mountings to help prevent noise which is generated by [AIR](#) pump operation. The [AIR](#) pump is powered from the vehicle battery by a dedicated relay and supplies approximately 10 to 15 kg/hr (22 to 33 lb/hr) of air when the engine is at idle speed and the ambient temperature is below 20°C (68°F).

Air is drawn into the [AIR](#) pump through vents in its front cover and is then passed through a foam filter. The air is delivered to the exhaust manifold on each side of the engine through a combination of plastic pipes and stainless steel tubes.

One second after the [AIR](#) pump is energised, the ECM switches on the [AIR](#) switching valve, which opens to allow vacuum from the [AIR](#) vacuum reservoir to be applied to the vacuum operated [AIR](#) control valve. When the vacuum is applied to the [AIR](#) control valve, it opens to

allow the air from the [AIR](#) pump through to the exhaust manifolds.

When the ECM switches off the [AIR](#) switching valve, the vacuum supply to the [AIR](#) control valve is cut-off and the valve closes to prevent further air being injected into the exhaust manifolds. With an approximate five second delay after as the [AIR](#) switching valve is closed, the ECM removes power from the [AIR](#) pump relay, and this in turn stops the [AIR](#) pump from operating.

SECONDARY AIR INJECTION SWITCHING VALVE

E62276

The ECM switches on the [AIR](#) switching valve with a one second delay after initiating [AIR](#) pump operation. When the [AIR](#) switching valve is open, a steady vacuum supply is allowed through to open the vacuum operated [AIR](#) control valve. When the ECM switches off the [AIR](#) switching valve, the valve closes and immediately shuts off the vacuum supply to the [AIR](#) control valve. The pump continues to operate for a further five seconds for system diagnostic purposes.

When the [AIR](#) switching valve is switched off, the vacuum supply line opens to atmosphere, and this causes the [AIR](#) switching valve to close automatically to prevent any further injection of air.

SECONDARY AIR INJECTION CONTROL VALVE

E62275

The injected air from the [AIR](#) pump is controlled by the [AIR](#) control valve. This allows the correct amount of air to be injected directly into the exhaust manifolds. The [AIR](#) control valve prevents exhaust gasses from blowing back into the [AIR](#) pump. Vacuum to the [AIR](#) switching valve is provided from the intake manifold vacuum by the [AIR](#) vacuum reservoir. A small bore vacuum hose provides the vacuum route between the [AIR](#) vacuum reservoir and [AIR](#) switching valve. A further small bore vacuum hose is used to connect the [AIR](#) switching valve to the [AIR](#) control valve.

The [AIR](#) control valve is assisted in operation by a vacuum source from the [AIR](#) vacuum reservoir located in the right-hand side of the engine bay. This assistance allows the actuation of the [AIR](#) control valve independently from the intake manifold vacuum levels available.

When the pressure in the exhaust system is higher than in the [AIR](#) system, the [AIR](#) control valve closes the circuit, and this protects the [AIR](#) system from exhaust gasses blowing back into the [AIR](#) system.

Vacuum to the [AIR](#) switching valve is provided from the intake manifold vacuum by the [AIR](#) vacuum reservoir. A small bore vacuum hose provides the vacuum route between the [AIR](#) vacuum reservoir and [AIR](#) switching valve. A further small bore vacuum hose is used to connect the [AIR](#) switching valve to the [AIR](#) control valve.

SECONDARY AIR INJECTION RESERVOIR

E62277

The [AIR](#) vacuum reservoir is included in the vacuum supply line between the intake manifold and the [AIR](#) switching valve. The [AIR](#) vacuum reservoir contains a one-way valve to stop vacuum leaking back towards the intake manifold side.

The [AIR](#) vacuum reservoir holds a constant vacuum so that the [AIR](#) control valve opens as soon as the [AIR](#) switching valve is switched on.

SECONDARY AIR INJECTION PRESSURE SENSOR

E75933

The [AIR](#) system is monitored by measuring the system pressure by using the [AIR](#) pressure sensor at several instances during its cycle of operation.

The [AIR](#) system pressure is measured before operation of the [AIR](#) pump. The [AIR](#) pump is then switched on and with a one second delay, the [AIR](#) switching valve is opened. After a stabilizing period, the system pressure is measured again, this time by taking the average of a one second duration of readings, and normalising for variations in battery voltage and atmospheric pressure. If the system pressure measured at this time has not risen enough with respect to the initial [AIR](#) pressure reading then a failure will be flagged.

A second pressure measurement is made after the requirement for [AIR](#) into the exhaust system has expired, but continuing on from the same period of [AIR](#) pump operation, i.e. the pump is left running, against a closed [AIR](#) switching valve. Again this pressure measurement is the average of a one second duration of readings normalised for variations in battery voltage and atmospheric pressure. If the system pressure measured at this time has not risen enough or has risen too much with respect to the system pressure during normal operation of [AIR](#) then a failure will be flagged.

A final pressure reading is taken after the [AIR](#) system has been switched off to ensure the system shuts down.

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Engine breather hoses ● Cyclone separator ● Exhaust gas recirculation (EGR) pipes (check for cracks) ● EGR valve ● Secondary air injection (AIR) pump ● Secondary air injection (AIR) valve 	<ul style="list-style-type: none"> ● Fuses ● Wiring harness ● Loose or corroded electrical connectors ● Sensor(s) ● Stepper motor(s) ● Secondary air injection (AIR) pump ● Secondary air injection (AIR) valve ● Engine control module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the customer concern and refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Engine cranks, but does not fire	<ul style="list-style-type: none"> ● Engine breather system disconnected/restricted 	Ensure the engine breather system is free from restriction and is correctly installed

Engine oil leaks	<ul style="list-style-type: none"> ● Engine breather system restricted 	Ensure the engine breather system is free from restriction and is correctly installed

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

NOTE: If DTCs are recorded and, after the pinpoint tests have been carried out, the fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Engine Emission Control - V6 3.0L Petrol - Secondary Air Injection (AIR) Control Valve

Removal and Installation

Removal

1. Remove the secondary air injection (AIR) control valve to exhaust manifold right-hand tube.
For additional information, refer to: [Secondary Air Injection \(AIR\) Control Valve to Exhaust Manifold Tube RH](#) (303-08B Engine Emission Control - V6 3.0L Petrol, Removal and Installation).
2. Raise and support the vehicle.
3. Disconnect the AIR switching valve electrical connector.

E63556

4. Disconnect the AIR switching valve vacuum hoses.

E63557

5. Detach the AIR wiring harness.

E63558

6. Disconnect the AIR control valve vacuum hose.

E63559

7. NOTE: Note the position of the timing marks on the AIR control valve and the AIR supply hose.

Disconnect the AIR supply hose.

E63560

8. Remove the AIR control valve and bracket assembly.

E63561

Installation

1. To install, reverse the removal procedure.

- Tighten to 8 Nm.

E63561

2. NOTE: For NAS vehicles only.

If required, carry out a short drive cycle.

For additional information, refer to: Powertrain Control Module (PCM) Short Drive Cycle Self-Test (303-14C, General Procedures).

Engine Emission Control - V6 3.0L Petrol - Secondary Air Injection (AIR) Control Valve to Exhaust Manifold Tube LH

Removal and Installation

Removal

1.  **WARNING:** Make sure to support the vehicle with axle stands.

Raise and support the vehicle.

2. **NOTE:** Note the position of the timing mark on the secondary air injection (AIR) control valve to exhaust manifold left-hand tube. The timing mark indicates the correct end of the AIR control valve to exhaust manifold left-hand tube that should be connected to the AIR control valve to exhaust manifold right-hand tube.

Disconnect the secondary air injection (AIR) control valve to exhaust manifold left-hand tube.

E63553

3. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).

4. Remove the AIR control valve to exhaust manifold left-hand tube from the left-hand exhaust manifold.

E63171

Installation

1. To install, reverse the removal procedure.

- Tighten to 35 Nm.

E63171

2. **NOTE:** Make sure that the timing mark on the AIR control valve to exhaust manifold left-hand tube is correctly aligned.

Tighten to 35 Nm.

Engine Emission Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Engine Emission Control - Overview

Description and Operation

OVERVIEW

The engine emission control system on the 4.2L engines (Supercharged and NA) comprise:

- Crankcase ventilation system
- [AIR \(secondary air injection\)](#) system

The crankcase ventilation system consists of two hoses, connected between the left-hand valve cover and the intake manifold and the right-hand valve cover and the air cleaner outlet pipe and a [PCV \(positive crankcase ventilation\)](#) valve located on the top on the [LH \(left-hand\)](#) engine cam cover. The [PCV](#) system recycles crankcase gases back through the engine where they mix with incoming air/fuel charge and help to reduce hydrocarbon emissions.

The [AIR](#) system comprises the following components:

- [AIR](#) pump
- [AIR](#) switching valve
- [AIR](#) control valve
- [AIR](#) vacuum reservoir
- [AIR](#) pump relay
- [AIR](#) pressure sensor (North American specification vehicles only)

Engine Emission Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Engine Emission Control - System Operation and Component Description

Description and Operation

System Operation

CRANKCASE VENTILATION

The engine is ventilated through a part load and a full load breather. The part load breather is a flexible composite hose connected between the [PCV \(positive crankcase ventilation\)](#) valve mounted above the oil separator in the [RH \(right-hand\)](#) bank camshaft cover and the induction elbow.

SECONDARY AIR INJECTION

[AIR \(secondary air injection\)](#) is fitted to the vehicle to reduce exhaust emissions to meet European Union (EU) Stage 4 and Federal Petrol Emission standards. The [AIR](#) system comprises:

- [AIR](#) pump
- [AIR](#) valve
- Associated pipes
- [AIR](#) pressure sensor (NAS only)

The [AIR](#) pump is used to provide a supply of air into the exhaust manifolds during the cold start period of the engine. The [AIR](#) cycle lasts for up to 65 seconds. The hot unburnt fuel particles leaving the combustion chamber mix with the air injected into the exhaust manifolds and immediately combust.

This subsequent combustion of the unburnt and partially burnt [CO \(carbon monoxide\)](#) and [HC \(hydrocarbon\)](#) particles help to reduce the emission of these pollutants from the exhaust system. The additional heat generated in the exhaust manifold also provides rapid heating of the exhaust system catalytic converters. The additional oxygen which is delivered to the catalytic converters also generates an exothermic reaction which causes the catalytic converters to reach their optimum operating temperature and 'light off' quickly.

The catalytic converters only start to provide effective treatment of emission pollutants when they reach an operating temperature of approximately 250°C (482°F) and need to be between temperatures of 400°C (752°F) and 800°C (1472°F) for optimum efficiency. Consequently, the heat produced by the [AIR](#) 'afterburning' reduces the time delay before the catalysts reach an efficient operating temperature.

EGR SYSTEM

The [EGR \(exhaust gas recirculation\)](#) system comprises of an [EGR](#) valve and exhaust manifold to [EGR](#) valve tube. The [EGR](#) system allows a measured quantity of exhaust gas to be directed back to the intake manifold. The exhaust gas is introduced to the incoming charge air in the intake manifold, where it mixes with the air/fuel mixture and lowers the peak gas temperature, reducing [NOX \(oxides of nitrogen\)](#) exhaust emissions. The gas is drawn through the exhaust manifold to [EGR](#) valve tube from the exhaust to the inlet manifold through the [EGR](#) valve. The [EGR](#) valve is electrically operated and is controlled through an input from the [ECM \(engine control module\)](#).

The [ECM](#) monitors the operation of the [EGR](#) system from inputs from the [MAP \(manifold absolute pressure\)](#) sensor and can detect high or low flow through the valve as a result of changes to the pressure readings.

High or low flow outside the expected range results in the setting of a [DTC \(diagnostic trouble code\)](#).

On vehicles without a supercharger the [MAP](#) sensor is mounted on the rear of intake manifold. On vehicles with a supercharger the [MAP](#) sensor is mounted on the rear of the throttle body elbow.)

Component Description

POSITIVE CRANKCASE VENTILATION VALVE

E48519

The [PCV](#) valve is a spring loaded valve that opens when the engine is under full load. Once open the valve allows crankcase gasses to flow to the intake manifold. The [PCV](#) valve also prevents reverse flow into the crankcase.

SECONDARY AIR INJECTION PUMP

E62274

The [AIR](#) pump is fitted on rubber mountings to help prevent noise which is generated by [AIR](#) pump operation. The [AIR](#) pump is powered from the vehicle battery by a dedicated relay and supplies approximately 10 to 15 kg/hr (22 to 33 lb/hr) of air when the engine is at idle speed and the ambient temperature is below 20°C (68°F).

Air is drawn into the [AIR](#) pump through vents in its front cover and is then passed through a foam filter. The air is delivered to the exhaust manifold on each side of the engine through a combination of plastic pipes and stainless steel tubes.

One second after the [AIR](#) pump is energized, the [ECM](#) switches on the [AIR](#) switching valve, which opens to allow vacuum from the [AIR](#) vacuum reservoir to be applied to the vacuum operated [AIR](#) control valve. When the vacuum is applied to the [AIR](#) control valve, it opens to allow the air from the [AIR](#) pump through to the exhaust manifolds.

When the [ECM](#) switches off the [AIR](#) switching valve, the vacuum supply to the [AIR](#) control valve is cut-off and the valve closes to prevent further air being injected into the exhaust manifolds. With an approximate five second delay after as the [AIR](#) switching valve is closed, the [ECM](#) removes power from the [AIR](#) pump relay, and this in turn stops the [AIR](#) pump from operating.

SECONDARY AIR INJECTION SWITCHING VALVE

E62276

The [ECM](#) switches on the [AIR](#) switching valve with a one second delay after initiating [AIR](#) pump operation. When the [AIR](#) switching valve is open, a steady vacuum supply is allowed through to open the vacuum operated [AIR](#) control valve. When the [ECM](#) switches off the [AIR](#) switching valve, the valve closes and immediately shuts off the vacuum supply to the [AIR](#) control valve. The pump continues to operate for a further five seconds for system diagnostic purposes.

When the [AIR](#) switching valve is switched off, the vacuum supply line opens to atmosphere, and this causes the [AIR](#) switching valve to close automatically to prevent any further injection of air.

SECONDARY AIR INJECTION CONTROL VALVE

E62275

The injected air from the [AIR](#) pump is controlled by the [AIR](#) control valve. This allows the correct amount of air to be injected directly into the exhaust manifolds. The [AIR](#) control valve prevents exhaust gasses from blowing back into the [AIR](#) pump. Vacuum to the [AIR](#) switching valve is provided from the intake manifold vacuum by the [AIR](#) vacuum reservoir. A small bore vacuum hose provides the vacuum route between the [AIR](#) vacuum reservoir and [AIR](#) switching valve. A further small bore vacuum hose is used to connect the [AIR](#) switching valve to the [AIR](#) control valve.

The [AIR](#) control valve is assisted in operation by a vacuum source from the [AIR](#) vacuum reservoir located in the right-hand side of the engine bay. This assistance allows the actuation of the [AIR](#) control valve independently from the intake manifold vacuum levels available.

When the pressure in the exhaust system is higher than in the [AIR](#) system, the [AIR](#) control valve closes the circuit, and this protects the [AIR](#) system from exhaust gasses blowing back into the [AIR](#) system.

Vacuum to the [AIR](#) switching valve is provided from the intake manifold vacuum by the [AIR](#) vacuum reservoir. A small bore vacuum hose provides the vacuum route between the [AIR](#) vacuum reservoir and [AIR](#) switching valve. A further small bore vacuum hose is used to connect the [AIR](#) switching valve to the [AIR](#) control valve.

SECONDARY AIR INJECTION RESERVOIR

E62277

The [AIR](#) vacuum reservoir is included in the vacuum supply line between the intake manifold and the [AIR](#) switching valve. The [AIR](#) vacuum reservoir contains a one-way valve to stop vacuum leaking back towards the intake manifold side.

The [AIR](#) vacuum reservoir holds a constant vacuum so that the [AIR](#) control valve opens as soon as the [AIR](#) switching valve is switched on.

SECONDARY AIR INJECTION PRESSURE SENSOR (NAS only)

The [AIR](#) system is monitored by measuring the system pressure by using the [AIR](#) pressure sensor at several instances during its cycle of operation.

The [AIR](#) system pressure is measured before operation of the [AIR](#) pump. The [AIR](#) pump is then switched on and with a one second delay, the [AIR](#) switching valve is opened. After a stabilizing period, the system pressure is measured again, this time by taking the average of a one second duration of readings, and normalizing for variations in battery voltage and atmospheric pressure. If the system pressure measured at this time has not risen enough with respect to the initial [AIR](#) pressure reading then a failure will be flagged.

A second pressure measurement is made after the requirement for [AIR](#) into the exhaust system has expired, but continuing on from the same period of [AIR](#) pump operation, i.e. the pump is left running, against a closed [AIR](#) switching valve. Again this pressure measurement is the average of a one second duration of readings normalized for variations in battery voltage and atmospheric pressure. If the system pressure measured at this time has not risen enough or has risen too much with respect to the system pressure during normal operation of [AIR](#) then a failure will be flagged.

A final pressure reading is taken after the [AIR](#) system has been switched off to ensure the system shuts down.

EGR VALVE

The [EGR](#) valve is a 4 pole 60 point stepper motor with an integral cooler unit which is mounted on the side of the induction elbow. The [EGR](#) valve receives four 12 Volt signals from the [ECM](#). The [EGR](#) valve is cooled by the return coolant flow from the electric throttle. The [EGR](#) valve is connected to the [LH \(left-hand\)](#) exhaust manifold via the gas transfer pipe.

Engine Emission Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Engine Emission Control

Diagnosis and Testing

Principle of Operation

For a detailed description of the Engine Emission Control system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (303-08 Engine Emission Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

[Engine Emission Control](#) (Description and Operation),
[Engine Emission Control](#) (Description and Operation),
[Engine Emission Control](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Engine breather hoses ● Cyclone separator ● Exhaust gas recirculation (EGR) pipes (check for cracks) ● EGR valve ● Secondary air injection (AIR) pump ● Secondary air injection (AIR) valve 	<ul style="list-style-type: none"> ● Fuses ● Wiring harness ● Loose or corroded electrical connectors ● Sensor(s) ● Stepper motor(s) ● Secondary air injection (AIR) pump ● Secondary air injection (AIR) valve ● Engine control module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the customer concern and refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Engine cranks, but does not fire	<ul style="list-style-type: none"> ● Engine breather system disconnected/restricted 	Ensure the engine breather system is free from restriction and is correctly installed
Difficult to start cold	<ul style="list-style-type: none"> ● Exhaust gas recirculation (EGR) valve stuck open 	Check for related DTCs and refer to the relevant DTC Index
Engine stalls soon after start	<ul style="list-style-type: none"> ● Breather system disconnected/restricted 	Ensure the engine breather system is free from restriction and is correctly installed
Engine stops/stalls	<ul style="list-style-type: none"> ● EGR valve stuck open 	Check for related DTCs and refer to the relevant DTC Index
Poor idle quality	<ul style="list-style-type: none"> ● EGR valve stuck open 	Check for related DTCs and refer to the relevant DTC Index
Engine hesitates/poor acceleration	<ul style="list-style-type: none"> ● EGR valve stuck open 	Check for related DTCs and refer to the relevant DTC Index
Poor throttle response	<ul style="list-style-type: none"> ● Breather system disconnected/restricted 	Ensure the engine breather system is free from restriction and is correctly installed
Excessive fuel consumption, black smoke, emissions	<ul style="list-style-type: none"> ● EGR valve stuck open ● EGR system not operating ● Engine breather system restricted 	Check for related DTCs and refer to the relevant DTC Index. Ensure the engine breather system is free from restriction and is correctly installed
Loud 'ticking' noise with engine running	<ul style="list-style-type: none"> ● EGR pipes cracked 	Inspect the EGR pipes, paying particular attention to the ribbed sections. Replace as required
Engine oil leaks	<ul style="list-style-type: none"> ● Engine breather system restricted 	Ensure the engine breather system is free from restriction and is correctly installed

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after the pinpoint tests have been carried out, the fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Engine Emission Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Exhaust Gas Recirculation (EGR) Valve

4.2L NA V8 - AJV8
Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the engine cover.
For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
3. Disconnect the EGR valve electrical connector.

4.  **WARNING:** Since injury such as scalding could be caused by escaping steam or coolant, allow the vehicle cooling system to cool prior to carrying out this procedure.

 **CAUTION:** Always plug any open connections to prevent contamination.

Disconnect the 2 EGR valve coolant hoses.

- Clamp the EGR coolant hoses to minimize coolant loss.
- Release the 2 clips.

5. Release the EGR valve to exhaust manifold pipe.

- Remove the 2 nuts.
- Remove and discard the gasket.

E64147

6. Release the EGR valve from the throttle body elbow.

- Remove the 2 bolts.
- Remove and discard the gasket.

E64148

7. Remove the EGR valve.

- Remove the 2 bolts.
- Remove and discard the gasket.

Installation

1. Attach the EGR valve to the EGR valve pipe.

- Clean the component mating faces.
- Install a new gasket.
- Tighten the bolts to 21 Nm (15 lb.ft).

E64148

2. Attach the EGR valve to the throttle body elbow.

- Clean the component mating faces.
- Install a new gasket.
- Tighten the bolts to 10 Nm (7 lb.ft).

E64147

3. Attach the EGR valve to exhaust manifold pipe.

- Clean the component mating faces.
- Install a new gasket.
- Tighten the nuts to 25 Nm (18 lb.ft).

4. Connect the coolant hoses.

- Secure with the clips.

5. Connect the electrical connector.

6. Install the engine cover.

For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).

7. Connect the battery ground cable and install the cover.

For additional information, refer to: Specifications (414-01 Battery, Mounting and Cables, Specifications).

8. Check and top-up the coolant.

9. **NOTE:** For NAS vehicles only.

If required, carry out a long drive cycle.

For additional information, refer to: Powertrain Control Module (PCM) Long Drive Cycle Self-Test (303-14C, General Procedures).

Intake Air Distribution and Filtering - TDV6 2.7L Diesel - Intake Air Distribution and Filtering - Overview

Description and Operation

Authoring Template

OVERVIEW

The intake air distribution system comprises:

- Twin [MAF \(mass air flow\)/IAT \(intake air temperature\)](#)
- Charge air temperature sensor
- Air cleaner and air cleaner housing
- Charge air cooler
- Twin turbochargers
- Intake port deactivation system

Air is drawn in from the vehicle exterior via the intake duct, at the front of the engine to the air cleaner box. The air passes through the air cleaner and exits the air cleaner housing via 2 ports. The clean air then passes through two [MAF/IAT](#) sensors and is drawn down to the turbochargers. The turbochargers force the air up to the charge air cooler via a T piece and out to the electric throttle, where it then flows into the respective intake air manifolds and down to the cylinder heads.

[Intake Air Distribution and Filtering](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. Verify the customer concern.
2. Visually inspect for obvious signs of mechanical or electrical damage.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Hoses and ducts (damage/connections) ● Air cleaner element (contaminated/blocked) ● Restricted air intake ● Seals and gaskets 	<ul style="list-style-type: none"> ● Mass Air Flow (MAF) sensor ● Secondary Air Injection (AIR), Manifold Absolute Pressure (MAP) sensors ● Throttle body ● Harness (security/damage) ● Connections (security/damage)

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Vehicle does not start/hard starting/poor performance	<ul style="list-style-type: none"> ● Restricted/blocked air intake ● Restricted/blocked air cleaner element 	Ensure the air intake system is free from blockage and is correctly installed. DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

- NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).
- NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: Inspect connectors for signs of water ingress, and pins for damage and/or corrosion.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Intake Air Distribution and Filtering - V6 3.0L Petrol - Intake Air Distribution and Filtering - Overview

Description and Operation

OVERVIEW

The air induction system comprises:

- Dirty air intake duct
- Air cleaner and housing
- [IMT \(intake manifold tuning\)](#) valves
- Air intake manifold
- Associated clean air ducts
- [MAP \(manifold absolute pressure\)](#)
- Electric throttle

Dirty air is drawn through the air intake mounted at the front [LH \(left-hand\)](#) side of the engine compartment and routed into the base of the air cleaner box. The air cleaner is a replaceable paper filter element which is accessed by removing the top of the air cleaner box. The air is drawn through the air cleaner out of the air cleaner box past the [MAF \(mass air flow\)](#) along a tube to the electric throttle. From the electric throttle the clean air is drawn to the intake manifold. The intake manifold is one unit which is divided into two separate halves. Each half supplies clean air to one bank of cylinders. Two [IMT](#) valves control the airways between the two halves of the intake manifolds.

There are two intake manifold tuning (IMT) valves, an upper and a lower, sometimes referred to as number one and two respectively. They are a two position (open and close) device used to create a variable air intake system. The [IMT](#) valve positions are switched by signals from the [ECM \(engine control module\)](#) to optimize torque across the engine's speed and load range. The upper [IMT](#) valve opens between 4,100 and 6,150 rpm while the lower [IMT](#) valve opens between 3,900 and 6,150 rpm.

Intake Air Distribution and Filtering - 4.2L NA V8 - AJV8 - Intake Air Distribution and Filtering - Overview

Description and Operation

Authoring Template

OVERVIEW

The 4.2 Liter NA V8 engine air intake and distribution system comprises:

- Air cleaner
- Air cleaner box
- Air Intake manifold
- Electronic throttle

The air cleaner box is located in front of the [LH \(left-hand\)](#) front wheel, inside the engine compartment and contains a replaceable paper filter element.

Dirty air is drawn through the air intake which is located behind the radiator grill on the [LH](#) side and into the air filter box past the paper filter element. Clean air is then passed over the [MAF \(mass air flow\)](#) sensor located in the ducting directly behind the air filter box, through the electric throttle and up to the air intake manifold where it is distributed to the individual cylinders.

The intake manifold is located on top of the engine between the two engine banks. The manifold is manufactured from a composite material with metal insert fixings. The intake manifold comprises a central chamber with eight tracts leading to the inlet ports on the engine.

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Hoses and ducts (damage/connections) ● Air cleaner element (contaminated/blocked) ● Restricted air intake ● Seals and gaskets 	<ul style="list-style-type: none"> ● Mass Air Flow (MAF) sensor ● Secondary Air Injection (AIR) Manifold Absolute Pressure (MAP) sensor ● Throttle body ● Harness (security/damage) ● Connections (security/damage)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the customer concern and refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Vehicle does not start/hard starting/poor performance	<ul style="list-style-type: none"> ● Restricted/blocked air intake ● Restricted/blocked air cleaner element 	Ensure the air intake system is free from blockage and is correctly installed. Install a new air cleaner element as necessary. Excessive intake noise	<ul style="list-style-type: none"> ● Intake pipe disconnected/damaged after the air cleaner ● Air cleaner assembly incorrectly assembled/damaged 	Check for correct installation and integrity of air intake system. Check for correct installation and integrity of the air cleaner assembly. REFER to: Air Cleaner (303-12A Intake Air Distribution and Filtering - 4.2L NA V8 - AJV8, Removal and Installation), Air Cleaner LH (303-12D, Removal and Installation), Air Cleaner RH (303-12D, Removal and Installation).

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• **NOTE:** If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are logged and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Intake Air Distribution and Filtering - 4.2L SC V8 - AJV8 - Intake Air Distribution and Filtering - Overview

Description and Operation

OVERVIEW

The engine air intake and distribution system comprises:

- Two air cleaner boxes
- Two air intakes
- Electric throttle
- A supercharger
- Two [MAF \(mass air flow\)](#) sensors
- Two supercharger charge air coolers

Air is supplied to the supercharger via the 2 air cleaners, air cleaner outlet pipes, throttle body intake pipe, throttle body and induction elbow. The supercharger delivers pressurized air to two separate charge air cooler units mounted onto the cylinder bank it supplies. Pressurized cooled air is fed from the charge air coolers directly into each inlet port. The supercharger is attached to the three mounting bosses between the two cylinder heads. The supercharger has a filled for life internal lubrication system. The supercharger is positively aligned with the drive belt by a doweled mounting bracket.

A [MAF](#) sensor is fitted at the outlet of each air cleaner box. The sensor provides an input to the [ECM \(engine control module\)](#). The intake elbow directs the metered airflow from the throttle body outlet (underside of the throttle body) into the intake of the supercharger.

A supercharger by-pass valve assembly is located between the supercharger outlet and the induction elbow. A butterfly valve inside the assembly is opened by a diaphragm actuator operated by vacuum feed from the elbow. At closed or partially open throttle positions, the butterfly valve opens, allowing the airflow from the two charge air cooler inlets to be directed back to the supercharger inlet. This action inhibits the supercharging effect and reduces engine torque. Progressive opening of the throttle causes the by-pass valve to gradually close.

Each cylinder bank is fitted with a charge air cooler which supplies pressurized air to the four cylinders. The inlet ports to the two charge air coolers are connected to the supercharger via the supercharger outlet pipe consisting of adjustable metal ducts with bonded rubber seals. The charge air coolers are water cooled via a radiator and water pump.

Evaporative Emissions - V6 3.0L Petrol - Evaporative Emissions - Overview

Description and Operation

OVERVIEW

The [EVAP \(evaporative emission\)](#) control system reduces the level of hydrocarbons released into the atmosphere by fuel vapor venting from the fuel tank. The system comprises a charcoal canister, purge valve and interconnecting vent pipes and hoses. The vent pipes are connected to the system components using quick release connectors.

Fuel vapor is generated by the fuel in the tank and the amount of vapor produced increases as the fuel heats up. Fuel vapor can flow freely to the charcoal canister via the tank venting system. The venting system consists of roll over valves and a liquid vapor separator mounted internally in the tank and then externally via a breather line. The breather line allows the fuel vapor to flow to the charcoal canister via a 'Y' piece mounted on the filler pipe.

On all vehicles the fuel vapor is restricted in its path to the charcoal canister but can flow freely during the refueling operation to atmosphere, via the filler opening.

The vapor passes into the charcoal canister where it is absorbed and stored by the charcoal. Because there is a limit to the amount of vapor the canister can contain, the fuel vapor is purged from the canister when the engine is running and burned in the engine.

Evaporative Emissions - V6 3.0L Petrol - Evaporative Emissions - System Operation and Component Description

Description and Operation

System Operation

The atmospheric pressure at the air intake vent of the system is higher than the inlet manifold pressure under all throttled engine running conditions. It is this pressure differential across the system that causes the air to flow through the air intake, through the purge system, and in to the engine.

The **ECM (engine control module)** waits until the engine is running above 40°C (104°F) coolant temperature with closed loop fuel operational before the purging process is activated. Under these conditions the engine should be running smoothly with no warm up enrichment. The purge valve duty (and flow) is initially ramped slowly because the vapor concentration is unknown (a sudden increase in purge could cause unstable engine running or cause it to stall due to an extremely "rich" air/fuel mixture.). The concentration is then determined from the amount of adjustment that the closed loop fueling is required to make to achieve the target Air Fuel Ratio (AFR). Once the concentration has been determined, the purge flow can be increased rapidly and the injected fuel can be proactively adjusted to compensate for the known purge vapor and the target AFR control is maintained.

When the purging process is active, fresh air is drawn into the charcoal canister via the vent hose connection and the spider trap.

Component Description

Charcoal Cannister

The charcoal canister is located in a central position, forward of the spare wheel. It is attached at the rear with two bolts which screw into the spare wheel carrier. At the front, the canister has two lugs which locate in the parking brake module support bracket.

The canister has a capacity of 1400cc (85.4 in3).

The canister has three ports which allow for the attachment of the atmospheric vent hose, the purge hose and the tank vent hose.

The canister contains a bed of activated charcoal or carbon. The charcoal is produced using special manufacturing techniques to treat the charcoal with oxygen. The oxygen treatment opens up millions of pores between the carbon atoms resulting in a highly porous charcoal with a very large effective surface area which is capable of absorbing large quantities of fuel vapor. Once treated the charcoal is known as 'activated' carbon or charcoal.

Purge Valve

The purge valve is located **LH (left-hand)** side of the engine, on a bracket which is attached to the cylinder block. The purge hose is routed from the purge valve, along the left hand side of the air intake manifold, to the elbow assembly which locates the electric throttle. The purge valve is controlled by the **ECM** and is operated when engine operating conditions are correct to allow purging of the charcoal canister. The purge valve is a solenoid operated valve which is closed when de-energized.

The purge hose is connected, at the right hand rear of the engine, with a quick release coupling to the purge line which runs parallel with the fuel feed line along the top of the fuel tank to the charcoal canister.

The purge hose continues from the purge valve and is routed to a connection on the air intake elbow assembly. The hose is connected to the elbow with a quick release connector.

The purge valve is **PWM (pulse width modulation)** at 10Hz by the **ECM**. At this high frequency, the pulses of purge gas flow into the inlet manifold in an almost a continuous flow. The valve operates between 7% and 100% duty or mark space ratio (% open time).

Evaporative Emissions - V6 3.0L Petrol - Evaporative Emissions

Diagnosis and Testing

For a detailed description of the evaporative emission system and operation, refer to the relevant Description and Operation section of the workshop manual. REFER to: Evaporative Emissions (303-13 Evaporative Emissions - V8 5.0L Petrol/V8 S/C 5.0L Petrol, Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault and may also cause additional faults in the vehicle being checked and/or the donor vehicle.

- **NOTE:** Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

1. Verify the customer concern.
2. Visually inspect for obvious signs of mechanical or electrical damage.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Fuel filler cap and seal ● Fuel filler neck ● DMTL fresh air filter (restriction, etc) ● Fuel tank (leaks, damage, etc) ● Fuel lines and joints, etc ● Carbon canister ● Purge valve ● Diagnostic module fuel tank leak (DMTL) pump module 	<ul style="list-style-type: none"> ● Fuses ● Connectors ● Harness ● Purge valve ● Diagnostic module fuel tank leak (DMTL) pump

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.
5. Where K-Line, Vacutec or other proprietary smoke test equipment is available, it should be utilized to assist with Evaporative Emissions System leak diagnosis.

Symptom Chart

Symptom	Possible Causes	Action
Difficulty in filling fuel tank	<ul style="list-style-type: none"> ● Restriction in the vapour line between the fuel tank and the carbon canister outlet/atmospheric port 	Check for restrictions/damage, etc (see visual inspection)
Fuel smell	<ul style="list-style-type: none"> ● System leak ● Purge valve inoperative 	Check for leaks, check the purge valve operation
'Check Fuel Filler Cap' displayed on Message Center	<ul style="list-style-type: none"> ● Fuel filler cap missing/not tightened after refuelling 	Check the fuel filler cap and seal

DTC Index

For a list of Diagnostic Trouble Codes (DTCs) that could be logged on this vehicle, please refer to Section 100-00.

Evaporative Leak OBD Fault Rectification Guide

Determine Which DTC Has Been Stored

Using the manufacturer approved diagnostic system, choose **diagnostic session**, then choose the following symptom paths : **Powertrain/engine system/fuel vapour and odor**, **Powertrain/engine system/fuel tank**, **Electrical/instruments/warning lamps/engine malfunction lamp/lamp illuminated**, **Powertrain/engine system/engine performance/fuel consumption high**

- **NOTE:** This guide covers DTCs that relate to evaporative leak monitoring, as listed in the table below

DTC	Description
P0442-00	DMTL small leak
P0447-00	DMTL COV electrical low (open)
P0448-00	DMTL COV electrical high
P0455-00	DMTL rough leak
P2401-00	DMTL pump electrical low (open)
P2402-00	DMTL pump electrical high
P2404-2F	DMTL noise fault
P2404-29	DMTL reference leak
P2405-00	DMTL reference current low
P2406-00	DMTL reference current high
P2450-00	DMTL COV stuck open
P2451-00	DMTL COV stuck closed
P240B-00	DMTL heater electrical low (open)
P240C-00	DMTL heater electrical high

Attempt To Replicate The Fault Using The "Fuel Leak Check" Forced Test

1. Record any DTCs that has been logged
2. Using the manufacturer approved diagnostic system, in the **Recommendations** tab run the **Fuel Leak Check** forced test

3. **3.** For the test to be successful the fuel level must be between 15% and 85%
4. **4.** During this procedure the engine must be off
5. **5.** The possible responses from the test and the associated DTCs are listed below
6. **6.** If again no fault is found it could suggest that the failure mode is a borderline condition (refer to section 3) or that it was caused by incorrect fitment of the fuel cap or the fuel filler neck is at fault therefore it is important not disturb the fuel cap
7. **7.** Disconnect purge pipe from the purge valve, observe the condition of connection (the seating and condition of the "O" ring) and then reconnect. Using the manufacturer approved diagnostic system, run **Purge Valve Self Test** (to clean the purge valve) then run the **Fuel Leak Check**
8. **8.** If the test failed, a smoke test is required to determine the cause of the leak

• **NOTE:** P240B & P240C are not included in the **Fuel Leak Check** forced test (these monitors run at every ignition on and complete within 30 seconds)

Response Description	ID	Equivalent DTC
Function running: Reference leak measurement	1	
Function running: Rough leak measurement	2	
Function running: Small leak measurement	3	
Function running: 2nd ref leak measurement	4	
Function running: COV Cleaning	5	
Function aborted due to conditions: Vbatt conditions not correct (too high/ low)	11	
Function aborted due to conditions: Variation Ref. I (reference current) too high	12	P2404-29
Function aborted due to conditions: DMTL electrical fault	13	P0447, P0448
Function aborted due to conditions: Maximum diagnostic time exceeded	14	
Function aborted due to conditions: Crash detected	15	
Function aborted due to conditions: Refuel detected	20	
Function aborted due to conditions: Filler cap opened	21	
Function aborted due to conditions: Engine start	23	
Function aborted due to conditions: Noisy current measurement	24	P2404-2F
Function aborted due to conditions: Ambient temp outside range	26	
Function aborted due to conditions: Ambient pressure outside range	27	
Function aborted due to conditions: Other conditions	29	
Function complete - Tight system, fault free	30	
Function complete - Fine leak detected	31	P0442
Function complete - Rough leak detected	32	P0455
Function complete - Module error	33	P2401, P2402, P2450, P2451, P2405, P2406, P2404-29
Function complete - Medium leak detected	34	P0442, P0455

Read The "Ranking values" To Determine How Far Away The Result Is From The Failure Threshold

9. **9.** When the **Fuel Leak Check** forced test has completed the test results (known as ranking values) will be displayed
10. **10.** These should be compared against the limits shown in the table below
11. **11.** If the test result is borderline then there is a risk that a failure will occur at a later date (during customer usage of the vehicle)
12. **12.** To avoid this the vehicle should be carefully checked for any small leaks

Ranking Value	Normal Result For Tight System	Leak Failure Condition
Rough Leak (40 thou+)	0 > = 50	>= 128
Small Leak (20 thou+)	0 > = 60	>= 128

TRACE THE ROOT CAUSE OF THE FAULT

The list below provides some suggested actions to help trace the root cause of the fault

Each action should be followed up with a **Fuel Leak Check** forced test (and ranking value check) in order to determine if any improvement has been made

DTC	Fault Description	Fault Rectification Actions after smoke test
P0442-00	DMTL small leak	<ul style="list-style-type: none"> ● 1. Inspect / refit filler cap after smoke test (inspect filler neck for correct fitment to pocket so that filler neck protrudes) ● 2. Run engine at idle; Using the manufacturer approved diagnostic system, run Purge Valve Self Test (to clean the purge valve) ● 3. Check that the DMTL module wiring connector has been installed correctly and that the seals around the connector body and individual wires are in good condition ● 4. Check all fuel system connections are correctly installed and secure ● 5. Visually inspect purge canister, purge pipes, fuel tank and filler neck for any obvious damage ● 6. Try isolating the purge valve by fitting a blanking plug to the purge pipe ● 7. Carry out a smoke test ● 8. Replace the DMTL module
P0447-00	DMTL COV electrical low (open)	<ul style="list-style-type: none"> ● 1. Check fuse ● 2. Check that fuse fits tightly into the fuse holder ● 3. Check that the DMTL module wiring connector has been fitted correctly ● 4. Check wiring harness continuity between DMTL module and ECU connectors ● 5. Replace DMTL module
P0448-00	DMTL COV electrical high	<ul style="list-style-type: none"> ● 1. Check wiring ● 2. Replace DMTL module
P0455-00	DMTL rough leak	<ul style="list-style-type: none"> ● 1. Inspect / refit filler cap after smoke test (inspect filler neck for correct fitment to pocket so that filler neck protrudes) ● 2. Run engine at idle; Using the manufacturer approved diagnostic system, run "Purge Valve Self Test" (to help clean the purge valve) ● 3. Check that the DMTL module wiring connector has been installed correctly and that the seals around the connector body and individual wires are in good condition (surprisingly, this is a potential leakage path!) ● 4. Check all fuel system connections are correctly installed and secure

DTC	Fault Description	Fault Rectification Actions after smoke test
		<ul style="list-style-type: none"> ● 5. Visually inspect purge canister, purge pipes, fuel tank and filler neck for any obvious damage ● 6. Try isolating the purge valve by fitting a blanking plug to the purge pipe ● 7. Carry out a smoke test ● 8. Replace DMTL module
P2401-00	DMTL pump electrical low (open)	<ul style="list-style-type: none"> ● 1. Check fuse ● 2. Check that fuse fits correctly into the fuse holder ● 3. Check that the DMTL module wiring connector has been fitted correctly ● 4. Check wiring harness continuity between DMTL module and ECU connectors ● 5. Replace DMTL module
P2402-00	DMTL pump electrical high	<ul style="list-style-type: none"> ● 1. Check wiring ● 2. Replace DMTL module
P2404-2F	DMTL noise fault	<ul style="list-style-type: none"> ● Replace DMTL module
P2404-29	DMTL reference leak	<ul style="list-style-type: none"> ● Replace DMTL module
P2405-00	DMTL reference current low	<ul style="list-style-type: none"> ● Replace DMTL module
P2406-00	DMTL reference current high	<ul style="list-style-type: none"> ● 1. Check for any blockages in the DMTL ventilation pipe & filter ● 2. Replace DMTL module
P2450-00	DMTL COV stuck open	<ul style="list-style-type: none"> ● Replace DMTL module
P2451-00	DMTL COV stuck close	<ul style="list-style-type: none"> ● Replace DMTL module
P240B-00	DMTL heater electrical low (open)	<ul style="list-style-type: none"> ● 1. Check fuse ● 2. Check that fuse fits tightly into the fuse holder ● 3. Check that the DMTL module wiring connector has been fitted correctly ● 4. Check wiring harness continuity between DMTL module and ECU connectors ● 5. Replace DMTL module
P240C-00	DMTL heater electrical high	<ul style="list-style-type: none"> ● 1. Check wiring ● 2. Replace DMTL module

Pre and 10MY Denso/Bosch PCM Systems

CAUTION: The Maximum pressure of the EVAP system is 0.07 bar **do not exceed**

• NOTE: Apart from the purge valve connection, it is recommended to smoke test the EVAP system without disturbing any joints associated with the system, this will determine the leak more accurately and quickly

- 1. Remove rear wheel arch liner to access fuel filler neck
- 2. On the fuel filler neck the DMTL filter will be visible as shown in picture. Unclip filter housing from fuel filler neck to gain better access to DMTL filter
- 3. Remove carefully the top of filter to expose filter and remove
- 4. Attach rubber adapter to tip of smoke machine nozzle to ensure tight seal to filter housing. Disconnect the purge pipe from purge valve; this will be an escape point for the smoke to exit
- 5. Allow tester to complete self-test and green READY light to turn ON 2. For best Tester performance; completely unwind Tester's supply hose
- 6. Press **Smoke** on control panel to fill EVAP system with smoke vapour. The control panel **Smoke** light will light indicating smoke production. The smoke setting is on a 15 minute timer. Pressing the **Smoke** button again turns Tester off. It is normal for the flow meter ball, while in the smoke mode, not to be as steady as when it is in the **Test** mode. Note: The pressure gauge is active only after smoke cycle is complete
- 7. Continue introducing smoke into the EVAP System until the flow meter's ball stops descending and this assures the system test pressure is met and smoke will appear from the purge pipe, then close off purge pipe with special tool (Test Adapter Hose/EVAP Port 310-142)

E139910

E139911

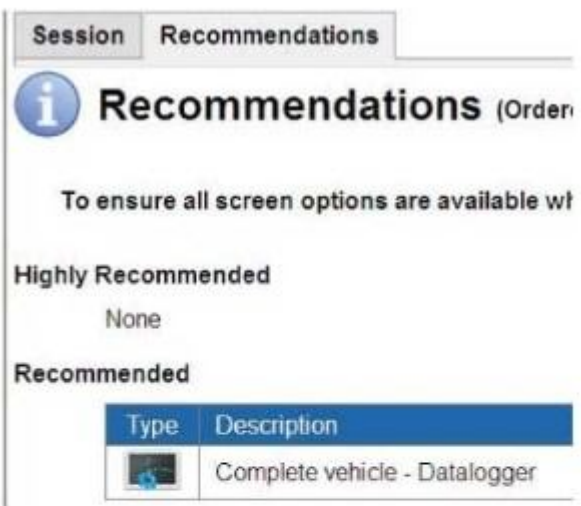

E139912

CAUTION: On some vehicles, the DMTL filter can not be removed, in these instances fill the system through the purge valve and smoke will appear from the filter

Pre 10MY Vehicles

On pre 10MY DMTL systems, Using the manufacturer approved diagnostic system, select **Measurement application** session then select the **Recommendations** tab which will give you access to **Datalogger**. Then select **Engine systems** then select the **Output state control** data-logger signal **Engine output 1 – diagnostic module – tank leakage -change over valve active** which will close the system. Then select **Engine output 1 – diagnostic module – tank leakage – pump active** this will pressurize the EVAP system

- Engine output 1 - engine management system warning lamp.
- Engine output 1 - malfunction indicator warning lamp.
- Engine output 1 - diagnostics module - tank leakage - test complete.
- Engine output 1 - diagnostics module - tank leakage - heater active.
- Engine output 1 - diagnostics module - tank leakage - pump active.
- Engine output 1 - diagnostics module - tank leakage - changeover valve active.
- Engine output 2 - heated exhaust gas oxygen heater active - bank 2.

E139916

E139913

10MY vehicles

On 10MY vehicles a smoke test application is available so therefore only smoke fill the system and then run the application

- 8. Follow the EVAP system path with the halogen light provided and looks for the smoke exiting the leak(s) or use the UV light provided and look for the dye deposited at the exact location of the leak(s)
- 9. Repair the leak(s) and perform the **Fuel Leak Check** application again or smoke test to verify repair, as well as to make sure there are no additional leaks in the EVAP system

The UltraTraceUV® smoke solution's dye feature is especially helpful when the leak is in an area that is not readily visible, as on the top of the fuel tank or behind a panel. Once you gain access to the area of the leak, wear the yellow UV glasses and shine the UV light provided to identify the exact location of the leak(s). Smoke exiting a very small leak is even easier to see with lower pressure. If you encounter smoke leaking out of an area but find it difficult to pinpoint exactly where the source of the leak is; try reducing the pressure in the system being tested by turning the Tester OFF and allow the pressure to dissipate. The longer a particular leak is allowed to leak, the more fluorescent dye material will be deposited at that leak. With some vapour system leaks, the leak may only present itself under vacuum and not under pressure. If equipment permits, test the system in both states. Purge valve faults [P0441, P0444, P0458 and P0459] should all inhibit DMTL leak test and therefore need to be resolved prior to any DMTL issues. For this reason, when smoke testing the vapour system, it should be sufficient to enter the system at the connection up stream of the purge valve. If no leak is found then testing the remainder of the system up to the purge valve is recommended

• NOTE: It may be possible to search for small leaks using a gas analyzer and looking for HC (hydro carbon) spikes. This should enable leaks to be detected in areas of the vapor system that our out of sight of the technician. The solenoid should be deactivated after five minutes to prevent potential damage. Check that connector and individual terminals are sealed correctly

Phase-One – (quantifying the leak)

E139914

1. Connect the tester supply hose to vehicle EVAP system. > Refer to appropriate vehicle application
2. Determine if the vehicle's EVAP system you are testing is governed by a .020" (0.5 mm) or .040" (1 mm) acceptable leak standard. Press the appropriate calibration standard on the tester's control panel and observe the position of the flow meter ball. > This function automatically turns off in 10 seconds
3. Position the flow meter's pointer flag so that it aligns with the measurement observed in step 2 above. > This sets PASS / FAIL mark
4. Close vehicle's EVAP Vent Solenoid. > Refer to appropriate vehicle application
5. Press TEST on control panel and fill EVAP system. > This introduces 5-minutes of nitrogen gas
6. Look for flow meter ball to stop descending indicating that the vehicle system is full. > Fill time 1-4 minutes depending on system volume
7. Compare flow meter ball reading to pointer flag. > ABOVE flag = FAIL (go to Phase-Two). > BELOW flag = PASS (test complete)

Testing With Pressure and Vacuum Decay

In addition to quantifying the leak with the Phase-One flow test, the Tester allows you the flexibility of testing the vehicle's EVAP system

by using either **Pressure Decay** or **Vacuum Decay** methods. Below are instructions for performing both decay tests

Pressure-Decay Test

• **NOTE:** The Pressure Decay test is best performed immediately after the Phase-one flow test, since the system has already built up pressure

At the completion of the Phase-one flow test, the EVAP system is fully pressurized, since the Phase-one test uses pressure to perform its flow test. Testing pressure decay with the Vacutec® 522B-J/LR is very simple. All you need to do is the following:

- 1. Allow tester to complete self-test and green **READY** light to turn ON
- 2. Connect Tester supply hose to vehicle EVAP system
- 3. Close vehicle's EVAP Vent solenoid > Refer to appropriate vehicle application
- 4. Press **VACUUM** switch on the tester control panel
 - **NOTE:** The vacuum switch is on a 30-second timer, which should be sufficient time to draw the appropriate vacuum from the EVAP system. Press VACUUM switch again if additional time is required
- 5. After vacuum timer turns off, observe the vacuum gauge for any decay (loss of vacuum) indicating a leak in the EVAP system

E139915

• **NOTE:** Disconnect the Tester from the vehicle after the Vacuum Decay Test. The fuel pressure in the vehicle's fuel tank is constantly changing due to the vehicle's fuel volatility and that could cause the Tester's pressure gauge to exceed its maximum reading limits

Evaporative Emissions - V6 3.0L Petrol - Evaporative Emission Canister

Removal and Installation

Special Tool(s)

Power train assembly jack

HTJ1200-2

Removal

-  **WARNING:** Make sure to support the vehicle with axle stands.

Raise and support the vehicle.

- Remove the left-hand shock absorber and spring assembly.
For additional information, refer to: [Shock Absorber and Spring Assembly \(204-02 Rear Suspension, Removal and Installation\)](#).

-  **CAUTION:** The brake caliper must be supported at all times. Failure to follow this instruction may result in damage to the vehicle.

Detach the left-hand rear brake caliper and anchor plate.

- Remove and discard the brake caliper anchor plate retaining bolts.

-  **CAUTION:** The brake caliper must be supported at all times. Failure to follow this instruction may result in damage to the vehicle.

- NOTE:** Mark the brake disc position in relation to the hub.

Remove the left-hand brake disc.

-  **CAUTION:** The brake caliper must be supported at all times. Failure to follow this instruction may result in damage to the vehicle.

Using a suitable tie strap, secure the left-hand brake caliper to the upper arm.

6. Disconnect the left-hand rear wheel speed sensor electrical connector.

7. Disconnect the headlamp levelling sensor.

8. Remove the front muffler.

For additional information, refer to: [Front Muffler](#) (309-00A Exhaust System - TDV6 2.7L Diesel, Removal and Installation).

9.  **WARNING:** Rotate the special tool height adjustment valve slowly. Failure to follow this instruction may result in personal injury.

Install the special tool to support the left-hand side of the rear subframe.

10. Remove the rear subframe left-hand reinforcement plate retaining bolts.

11. Remove and discard the rear subframe left-hand rear retaining bolt.

12. Remove the rear subframe left-hand reinforcement plate.

- Remove and discard the rear subframe left-hand front retaining bolt.

13.  **WARNING:** Rotate the special tool height adjustment valve slowly. Failure to follow this instruction may result in personal injury.

• **CAUTIONS:**

 Make sure the rear subframe weight is evenly supported on the special tool. Failure to follow this instruction may result in damage to the vehicle.

 Make sure when lowering the rear subframe damage does not occur to the surrounding components. Failure to follow this instruction may result in damage to the vehicle.

Using the special tool, lower the left-hand side of the rear subframe to a maximum of 152mm.

14. **NOTE:** Non federal market vehicles only.

• **NOTE:** Rear subframe shown removed for clarity.

Remove the fuel pump driver module.

- Disconnect the electrical connection.
- Remove 1 screw.

15. NOTE: Non federal market vehicles only.

- NOTE: Rear subframe shown removed for clarity.

Remove the evaporative emissions canister.

- Disconnect the 2 quick release connectors.
- Remove the 2 nuts.

16. NOTE: Rear subframe shown removed for clarity.

- NOTE: Federal market vehicles only.

Disconnect the evaporative emission canister vent solenoid vapor hose.

17. NOTE: Rear subframe shown removed for clarity.

- NOTE: Federal market vehicles only.

Disconnect the evaporative emission canister vent solenoid electrical connector.

18. NOTE: Rear subframe shown removed for clarity.

- NOTE: Federal market vehicles only.

Disconnect the evaporative emission canister vapor pipes.

19. NOTE: Rear subframe shown removed for clarity.

• NOTE: Federal market vehicles only.

Detach the evaporative emission canister.

20. NOTE: Federal market vehicles only.

Remove the evaporative emission canister.

Installation

1. To install, reverse the removal procedure.

- Tighten to 7 Nm.

2. NOTE: Install new rear subframe retaining bolts.

Loosely install the rear subframe left-hand front retaining bolt.

- Install the rear subframe left-hand reinforcement plate.

3. NOTE: Install new rear subframe retaining bolts.

Install the rear subframe left-hand rear retaining bolt.

- Tighten to 125 Nm.

4. Install the rear subframe left-hand reinforcement plate retaining bolts.

- Tighten to 47 Nm.

E31121

5. Tighten the rear subframe left-hand front retaining bolt.

- Tighten to 125 Nm.

E63023

6.  CAUTION: The brake caliper must be supported at all times. Failure to follow this instruction may result in damage to the vehicle.

- NOTE: Remove and discard the securing tie strap.
- NOTE: Install new brake caliper anchor plate retaining bolts.

Install the left-hand brake caliper and anchor plate.

- Tighten the bolts to 103 Nm.

E46510

Evaporative Emissions - V6 3.0L Petrol - Evaporative Emission Canister Purge Valve

Removal and Installation

Removal

1. Disconnect the evaporative emission canister purge valve hose.

2. Detach the evaporative emission canister purge valve hose.

3. Disconnect the evaporative emission canister purge valve electrical connector.

4. Remove the evaporative emission canister purge valve and bracket assembly.

- Detach the wiring harness from the bracket.
- Detach the vacuum hose retaining clip from the stud.
- Remove the retaining nut and bolt.

E99141

5. Remove the evaporative emission canister purge valve.

- Disconnect the evaporative emission canister purge valve hose.

E64949

Installation

1. To install, reverse the removal procedure.

- Tighten to 10 Nm.

E64948

Evaporative Emissions - V6 3.0L Petrol - Evaporative Emission Canister Vent Solenoid

Removal and Installation

Removal

• WARNINGS:

 Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

 Do not carry or operate cellular phones when working on or near any fuel related components. Highly flammable vapours are always present and may ignite. Failure to follow these instructions may result in personal injury.

 **CAUTION:** Make sure the working surfaces are thoroughly clean to avoid contamination of the sensitive components.

1.  **WARNING:** Make sure to support the vehicle with axle stands.

Raise and support the vehicle.

2. Disconnect the evaporative emission canister vent solenoid vapor hose.

3. Disconnect the evaporative emission canister vent solenoid electrical connector.

4. Remove the evaporative emission canister vent solenoid.

- Remove and discard the evaporative emission canister vent solenoid O-ring seal.

Installation

1. NOTE: Install a new O-ring seal.

To install, reverse the removal procedure.

- Tighten to 6 Nm.

Evaporative Emissions - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Evaporative Emissions - Overview

Description and Operation

OVERVIEW

The [EVAP \(evaporative emission\)](#) control system reduces the level of hydrocarbons released into the atmosphere by fuel vapor venting from the fuel tank. The system comprises a charcoal canister, purge valve and interconnecting vent pipes and hoses. The vent pipes are connected to the system components using quick release connectors.

Fuel vapor is generated by the fuel in the tank and the amount of vapor produced increases as the fuel heats up. Fuel vapor can flow freely to the charcoal canister via the tank venting system. The venting system consists of roll over valves and a liquid vapor separator mounted internally in the tank and then externally via a breather line. The breather line allows the fuel vapor to flow to the charcoal canister via a 'Y' piece mounted on the filler pipe.

On NAS vehicles the vapor generated in the fuel tank during refueling flows without restriction to the charcoal canister.

On all vehicles except NAS, the vapor is restricted in its path to the charcoal canister but can flow freely during the refueling operation to atmosphere, via the filler opening.

The vapor passes into the charcoal canister where it is absorbed and stored by the charcoal. Because there is a limit to the amount of vapor the canister can contain, the fuel vapor is purged from the canister when the engine is running and burned in the engine.

All NAS vehicles have a fuel tank leakage monitoring system. This is a legislative requirement. The fuel tank leakage monitoring system periodically checks the [EVAP](#) system and the fuel tank for leaks when the ignition is switched off. The fuel tank leakage monitoring system comprises the previously described components of the [EVAP](#) system with the addition of a fuel tank leakage monitoring pump and a fuel tank leakage monitoring filter.

Evaporative Emissions - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Evaporative Emissions - System Operation and Component Description

Description and Operation

System Operation

The atmospheric pressure at the air intake vent of the system is higher than the inlet manifold pressure under all throttled engine running conditions. It is this pressure differential across the system that causes the air to flow through the air intake, through the purge system, and in to the engine.

The [ECM \(engine control module\)](#) waits until the engine is running above 40°C (104°F) coolant temperature with closed loop fuel operational before the purging process is activated. Under these conditions the engine should be running smoothly with no warm up enrichment. The purge valve duty (and flow) is initially ramped slowly because the vapor concentration is unknown (a sudden increase in purge could cause unstable engine running or cause it to stall due to an extremely "rich" air/fuel mixture.). The concentration is then determined from the amount of adjustment that the closed loop fueling is required to make to achieve the target Air Fuel Ratio (AFR). Once the concentration has been determined, the purge flow can be increased rapidly and the injected fuel can be proactively adjusted to compensate for the known purge vapor and the target AFR control is maintained.

When the purging process is active, fresh air is drawn into the charcoal canister via the tank leakage detection valve atmospheric vent connection and its filter on NAS vehicles or, via the vent hose connection and the spider trap on non NAS vehicles.

Tank Leakage Detection

The tank leakage detection system is a legislative requirement for NAS vehicles. The tank leakage detection system periodically checks the [EVAP \(evaporative emission\)](#) system and the fuel tank for leaks when the ignition is switched off. The tank leakage detection system comprises the previously described components of the [EVAP](#) system with the following additional components; a tank leakage detection pump and a tank leakage detection filter.

To check the fuel tank and the [EVAP](#) system for leaks, the [ECM](#) operates the tank leakage detection pump and monitors the current draw. Initially, the [ECM](#) establishes a reference current by pumping air through the reference orifice and back to atmosphere. Once the reference current is determined, the [ECM](#) closes the normally open valve which seals the [EVAP](#) system. The purge valve remains de-energized and is therefore closed. The output from the air pump is diverted from the reference orifice and into the [EVAP](#) system.

When the normally open valve is closed, the load on the air pump falls to zero. Providing there are no leaks, the air pump will begin to pressurize the [EVAP](#) system and the load and current draw in the pump increases. By monitoring the rate and level of the current increase, the [ECM](#) can determine if there is a leak in the [EVAP](#) system.

During normal vehicle operation, 15 seconds after the engine has started, the [ECM](#) energizes the heating element in the pump to prevent condensation formation and possible incorrect readings. The heater remains energized until either the engine and ignition are off (if no tank leakage detection test is running) or until after the tank leakage detection test is completed.

Leaks are classified as:

- Minor - equivalent to a hole diameter of 0.5 to 1.0 mm (0.02 to 0.04 in)
- Major - equivalent to hole diameter of 1.0 mm (0.04 in) or greater.

The [ECM](#) performs a check for major leaks each time the ignition is switched off, providing the following conditions are met:

- The vehicle speed is zero
- The engine speed is zero
- The pressure altitude (70 kPa (10.15 lbf/in²) derived from engine load calculations) is below 3047 m (10000 feet)
- The ambient temperature is between 0 and 40°C (32 and 104°F)
- The charcoal canister load factor is 2.5 or less (where the load factor is a measure, between -1 and +30, of the fuel vapor stored in the charcoal canister. Where -1 is 0% fuel vapor, 0 is stoichiometric fuel vapor level and +30 is 100% saturated with fuel vapor.
- The fuel tank level is valid and between 15 and 85% of nominal capacity
- The engine running time during the previous cycle was more than 10 minutes
- The battery voltage is between 10 and 15 volts
- The last engine off time was more than 180 minutes
- No errors are detected with the [EVAP](#) components, the ambient air temperature and the fuel level.

• **NOTE:** A leak test can be performed using the Jaguar approved diagnostic system. This overrides the above conditions and is useful for checking correct system and component operation.

The [ECM](#) performs a check for minor leaks after every 2nd major leak check or after refueling is detected.

When the leak check is complete, the [ECM](#) stops the tank leakage detection pump and opens (de-energizes) the normally open valve.

If the fuel filler cap is opened or refueling is detected during the leak check, by a sudden drop in the current draw or a rise in the fuel level, the [ECM](#) aborts the leak check.

If a leak is detected during the check, the [ECM](#) stores an appropriate fault code in its memory. If a leak is detected on two consecutive checks, the [ECM](#) illuminates the [MIL \(malfunction indicator lamp\)](#) in the instrument cluster on the next drive cycle.

The duration of a leak check can be between 60 and 600 seconds depending on the results and fuel tank level.

Component Description

Tank Leakage Detection Pump

E67816

The tank leakage detection pump is connected to the atmospheric vent of the charcoal canister and incorporates a [PTC \(positive temperature coefficient\)](#) heating element, a normally open valve and a reference orifice.

The tank leakage detection filter protects the pump from dust being drawn into the system when the pump is being operated. The filter is located on the fuel filler head and is connected to the tank leakage detection pump by a hose.

The tank leakage detection pump is only operated when the ignition is switched off and is controlled by the [ECM](#). The [ECM](#) also monitors the electric air pump operation and the normally open valve for faults. The tank leakage detection test is performed after the engine has stopped following a 10 minute run, providing that the vehicle fuel tank is between 15 and 85 percent full, the ambient temperature is above 0°C (32°F) and less than 40°C (104°F) and the vehicle was not started for at least 3hrs prior to this run.

The tank leakage detection pump is driven to pressurize the fuel tank and the current is measured with the change-over valve in different states.

A comparison of the current draw in each state indicates the degree of any leak, and the [ECM](#) then sets the appropriate [DTC \(diagnostic trouble code\)](#).

Charcoal Cannister

The charcoal canister is located in a central position, forward of the spare wheel. It is attached at the rear with two bolts which screw into the spare wheel carrier. At the front, the canister has two lugs which locate in the parking brake module support bracket.

The canister on ROW vehicles has a capacity of 1400cc (85.4 in³). The canister on NAS vehicles has a capacity of 3000cc (183 in³).

The canister has three ports which allow for the attachment of the atmospheric vent hose, the purge hose and the tank vent hose. On NAS vehicles the atmospheric vent hose connection allows for the attachment of the tank leakage detection pump.

The canister contains a bed of activated charcoal or carbon. The charcoal is produced using special manufacturing techniques to treat the charcoal with oxygen. The oxygen treatment opens up millions of pores between the carbon atoms resulting in a highly porous charcoal with a very large effective surface area which is capable of absorbing large quantities of fuel vapor. Once treated the charcoal is known as 'activated' carbon or charcoal. The charcoal canister on NAS vehicles uses a higher grade charcoal to meet the requirements of LEV2 emission regulations.

Purge Valve

The purge valve is located [RH \(right-hand\)](#) side of the engine, on a bracket which is attached to the water pump. The purge hose is routed from the purge valve to the electric throttle. The purge valve is controlled by the [ECM](#) and is operated when engine operating conditions are correct to allow purging of the charcoal canister. The purge valve is a solenoid operated valve which is closed when de-energized.

The purge hose is connected, at the front [RH](#) side of the engine, with a quick release coupling to the purge line which runs parallel with the fuel feed line along the top of the fuel tank to the charcoal canister.

The purge hose continues from the purge valve and is routed to a connection on the air intake elbow assembly. The hose is connected to the elbow with a quick release connector.

The purge valve is [PWM \(pulse width modulation\)](#) at 10Hz by the [ECM](#). At this high frequency, the pulses of purge gas flow into the inlet manifold in an almost a continuous flow. The valve operates between 7% and 100% duty or mark space ratio (% open time).

On NAS vehicles the system does not include a pressure test point. Pressure testing of the purge valve hose is achieved by disconnecting the purge valve joint on the underside of the vehicle, forward of the fuel tank and connecting a special tool to allow the system to be pressure tested. The test performs a pressure test on the purge hose connection forward of the fuel tank back to the charcoal canister. The special tool is then connected to the purge hose connection forward of the fuel tank to perform a pressure test on the purge hose to the purge valve.

Evaporative Emissions - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Evaporative Emissions

Diagnosis and Testing

Principles of Operation

For a detailed description of the Evaporative Emissions system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (303-13 Evaporative Emissions - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

[Evaporative Emissions](#) (Description and Operation),
[Evaporative Emissions](#) (Description and Operation),
[Evaporative Emissions](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Fuel filler cap and seal ● Fuel filler neck ● Diagnostic Monitoring of Tank Leakage (DMTL) fresh air filter (restriction, etc) ● Fuel tank (leaks, damage, etc) ● Fuel lines and joints, etc ● Carbon canister ● Purge valve ● DMTL pump module 	<ul style="list-style-type: none"> ● Fuses ● Connectors ● Harnesses ● Purge valve ● DMTL pump

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, and there are clear symptoms, refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) then proceed to the DTC Index.
5. • NOTE: On all vehicles equipped with Diagnostic Monitor Tank Leakage (DMTL), there is a requirement to blank off the ventilation port (large diameter stub pipe) of the DMTL module, to prevent mis-diagnosis when carrying out a smoke test.
5. Where K-Line, Vacutec or other proprietary smoke test equipment is available, it should be utilised to assist with Evaporative Emissions System leak diagnosis.

Symptom Chart

Symptom	Possible Cause	Action

Fuel smell	<ul style="list-style-type: none"> ● System leak ● Purge valve inoperative 	Check for leaks, check the purge valve operation
'Check Fuel Filler Cap' displayed on Message Center	<ul style="list-style-type: none"> ● Fuel filler cap missing/not tightened after refuelling 	Check the fuel filler cap and seal

DTC Index

CAUTION: When probing connectors to take measurements in the course of the diagnostic tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: If the module or a component is suspect and the vehicle remains under the manufacturer warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Evaporative Emissions - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Evaporative Emission Canister

Removal and Installation

Removal

WARNING: Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

1. WARNING: Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

2. Remove the rear differential.

For additional information, refer to: Axle Assembly (205-02, Removal and Installation).

3. CAUTION: Always plug any open connections to prevent contamination.

• **NOTE:** Sub-frame shown removed for clarity.

Disconnect the evaporative emissions canister.

- Disconnect the 3 lines.
- Disconnect the 2 electrical connectors.

4. Remove the fuel pump driver module.

- Remove the clip.

5. NOTE: Sub-frame shown removed for clarity.

Remove the evaporative emissions canister.

- Remove the 3 nuts.

Installation

1. Install the evaporative emissions canister.

- Torque: 10 Nm (7 lb.ft)

2. Install the fuel pump driver module.

3. Connect the evaporative emissions canister.

4. Install the rear differential.

For additional information, refer to: Axle Assembly (205-02, Removal and Installation).

Evaporative Emissions - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Evaporative Emission Canister Purge Valve

4.2L NA V8 - AJV8
Removal and Installation

Removal

1. Remove the engine cover.
For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
2. Release the 2 electrical connectors.

3.  **CAUTION:** Before disconnecting or removing the components, make sure the area around the joint faces and connections are clean. Plug open connections to prevent contamination.

Disconnect the evaporative emission canister purge valve outlet line at the throttle body elbow.

4.  **CAUTION:** Before disconnecting or removing the components, make sure the area around the joint faces and connections are clean. Plug open connections to prevent contamination.

Disconnect the evaporative emission canister purge valve inlet line.

5. Remove the evaporative emission canister purge valve assembly.

- Disconnect the electrical connector.
- Remove the 2 nuts.

6. NOTE: Do not disassemble further if the component is removed for access only.

- NOTE: Note the fitted position.

Remove the evaporative emission canister purge valve.

- Remove the bolt.

Installation

1. NOTE: Make sure that this component is installed to the noted removal position.

Install the evaporative emission canister purge valve.

- Tighten the bolt to 10 Nm.

2. Install the evaporative emission canister purge valve assembly.

- Tighten the nuts to 10 Nm.
- Connect the electrical connector.

3. Connect the evaporative emission canister purge valve lines.

4. Secure the electrical connectors.

5. Clean the component mating faces.

- Install the engine cover.

Evaporative Emissions - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Evaporative Emission Canister Purge Valve

4.2L SC V8 - AJV8
Removal and Installation

Removal

• NOTE: Removal steps in this procedure may contain installation details.

1. Refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Refer to: [Throttle Body](#) (303-04B Fuel Charging and Controls - 4.2L SC V8 - AJV8, Removal and Installation).

3.

4.

5.

6. Torque: 10 Nm

Installation

1. To install, reverse the removal procedure.

Electronic Engine Controls - TDV6 2.7L Diesel - Electronic Engine Controls - Overview

Description and Operation

OVERVIEW

The V6 Diesel engine has an engine management system controlled by an [ECM \(engine control module\)](#) and is able to monitor, adapt and precisely control the fuel injection. The [ECM](#) uses multiple sensor inputs and precision control of actuators to achieve optimum performance during all driving conditions.

The [ECM](#) controls fuel delivery to all 6 cylinders via a Common Rail (CR) injection system. The CR system uses a fuel rail to accumulate highly pressurized fuel and feed the 6, electronically controlled injectors. The fuel rail is located in close proximity to the injectors, which assists in maintaining full system pressure at each injector at all times.

[BJB \(battery junction box\)](#)[ABS \(anti-lock brake system\)](#)[IAT \(intake air temperature\)](#)[AJB \(auxiliary junction box\)](#)[APP \(accelerator pedal position\)](#)[KS \(knock sensor\)](#)[ECT \(engine coolant temperature\)](#)[MAF \(mass air flow\)](#)

The [ECM](#) uses the drive by wire principle for acceleration control. There are no control cables or physical connections between the accelerator pedal and the engine. Accelerator pedal demand is communicated to the [ECM](#) by two potentiometers located in a throttle position sensor.

The [ECM](#) uses the two signals to determine the position, rate of movement and direction of movement of the pedal. The [ECM](#) then uses this data, along with other engine information from other sensors, to achieve the optimum engine response.

The [ECM](#) processes information from the following input sources:

- [CKP \(crankshaft position\)](#) sensor
- [CMP \(camshaft position\)](#) sensor
- Manifold air temperature and pressure
- Coolant temperature
- Oil temperature
- Inlet air flow and temperature
- Fuel rail temperature
- [KS](#) (1 per cylinder bank)

The [ECM](#) outputs controlling signals to the following sensors and actuators:

- Fuel injectors
- Cooling fan control
- Electronic Throttle
- Electronic vane controlled turbo
- Port deactivation
- Fuel pressure control valve
- Fuel volume control valve
- Electronic [EGR \(exhaust gas recirculation\)](#)
- Glow plugs.

System Operation

DIESEL PARTICULATE FILTER (DPF) CONTROL

Vehicles are fitted with a Diesel Particulate Filter (DPF) which collects the particulate matter produced during the combustion process and reduces the particulates entering the atmosphere.

The DPF is located in the exhaust system, downstream of the catalytic converter. A major feature of the DPF is its ability for regeneration. Regeneration is the burning of particulates trapped by the filter to prevent obstruction to the free flow of exhaust gasses. The regeneration process is controlled by the [ECM](#) and takes place at calculated intervals and is not noticeable by the driver of the vehicle.

Regeneration is most important, since an overfilled filter can damage the engine through excessive exhaust back pressure and can itself be damaged or destroyed.

The exhaust gas and DPF temperatures are controlled by the DPF software located in the [ECM](#). The DPF software monitors the load status of the DPF based on driving style, distance travelled and signals from a differential pressure sensor and temperature sensors located before and after the DPF in the exhaust system. When the particulate loading of the DPF reaches predetermined levels, the DPF is actively regenerated by adjusting, in conjunction with the [ECM](#), various engine control functions such as:

- fuel injection
- intake air throttle
- [EGR](#)
- turbocharger boost pressure control.

The regeneration process is possible because of the flexibility of the common-rail fuel injection engine which provides precise control of fuel flow, fuel pressure and injection timing which are essential requirements to promote the efficient regeneration process.

The [ECM](#) contains the DPF software which controls and monitors the DPF and the regeneration process. The software is broken down into three separate modules; a DPF supervisor module, a DPF fuel management module and a DPF air management module, which interact with each other to provide precise DPF control.

These three modules are controlled by a fourth software module known as the DPF co-ordinator module. The co-ordinator module manages the operation of the other modules when an active regeneration is requested. The DPF supervisor module is a sub-system of the DPF co-ordinator module.

The DPF co-ordinator module reacts to a regeneration request from the supervisor module by initiating and controlling the following DPF regeneration requests:

- [EGR](#) cut-off
- Turbocharger boost pressure control
- Engine load increase
- Control of air pressure and temperature in the intake manifold
- Fuel injection control.

When the supervisor module issues a regeneration request, the co-ordinator module requests [EGR](#) cut-off and a regeneration specific turbocharger boost pressure control. It then waits for a feedback signal from the [EGR](#) system confirming that the [EGR](#) valve is closed.

• **NOTE:** The [EGR](#) valve is open at idle to allow reduced NO. [EGR](#) is not used during part load due to intake manifold contamination.

When the [EGR](#) valve is closed, the co-ordinator module initiates requests to increase engine load by controlling the intake air temperature and pressure.

Once confirmation is received that intake conditions are controlled or a calibration time has expired, the co-ordinator module then changes to a state awaiting an accelerator pedal release manoeuvre from the driver. If this occurs or a calibration time has expired, the co-ordinator module generates a request to control fuel injections to increase exhaust gas temperature.

The DPF air management module controls the following functions:

- [EGR](#) control
- Turbocharger boost pressure control
- Intake air temperature and pressure control.

During active regeneration, the [EGR](#) operation is disabled and the closed-loop activation of the turbocharger boost controller is calculated. The air management module controls the air in the intake manifold to a predetermined level of pressure and temperature. This control is required to achieve the correct in-cylinder conditions for stable and robust combustion of the post injected fuel.

Restricting the air intake during DPF regeneration has the following functions:

- Increase in engine load
- Slower combustion
- Reduction in the mass of air taken in
- A reduction in the speed of the exhaust gases and therefore an increase in the time for which the gases are in the catalytic converter.

The module controls the intake air temperature by actuating the [EGR](#) throttle and by adjustment of the turbocharger boost pressure control.

Component Description

Engine Control Module

The [ECM](#) is located in the plenum area attached to the bulkhead. The [ECM](#) is always on the opposite side to the hand of drive.

Inputs

The [ECM](#) has the following inputs:

- Engine Coolant Temperature
- [MAF](#) (2 off)
- Stop lamp switch (via [ABS](#) module on [CAN](#)) and hardwired to the [ECM](#)
- [IAT](#) (intake air temperature)
- Throttle Pedal Position 1
- Throttle Pedal Position 2
- Electronic throttle Position
- Engine speed and position sensor ([CKP](#))
- [CMP](#) sensor
- Engine Oil Temperature
- Speed Control Switches (resistive ladders)
- Vehicle Speed (via [CAN](#))
- Generator Monitor

- [RCM](#)
- [MAP \(manifold absolute pressure\)](#)
- [KS \(4 off\)](#)
- Fuel temperature and pressure
- Water in fuel sensor
- Boost air temperature
- Park/neutral switch

Outputs

The [ECM](#) outputs to the following:

- Throttle actuator
- Fuel injectors (6 off)
- [EGR](#) Valves
- Electric cooling fan
- Fuel pump relay
- Starter relay
- Air conditioning condenser fan module
- EMS Main relay
- Electric fan control
- Generator control
- Glow plugs
- Fuel volume control valve
- Fuel pressure control valve
- Active engine mounts
- Port deactivation control solenoid valve

The [ECM](#) connected to the vehicle harnesses via three connectors. The [ECM](#) contains data processors and memory microchips. The output signals to the actuators are in the form of ground paths provided by driver circuits within the [ECM](#). The [ECM](#) driver circuits produce heat during normal operation and dissipate this heat via the casing. Some sensors receive a regulated voltage supplied by the [ECM](#). This avoids incorrect signals caused by voltage drop during cranking.

The [ECM](#) performs self diagnostic routines and stores fault codes in its memory. These fault codes and diagnostics can be accessed using the Jaguar approved diagnostic system. If the [ECM](#) is to be replaced, the new [ECM](#) is supplied 'blank' and must be configured to the vehicle using the Jaguar approved diagnostic system. A 'flash' [EEPROM \(electrically erasable programmable read only memory\)](#) allows the [ECM](#) to be externally configured, using the Jaguar approved diagnostic system, with market specific or new tune information. The current engine tune data can be accessed and read using the Jaguar approved diagnostic system.

When a new [ECM](#) is fitted, it must also be synchronized to the immobilization control module using the Jaguar approved diagnostic system. [ECM](#)'s cannot be 'swapped' between vehicles.

The [ECM](#) is connected to the engine sensors which allow it to monitor the engine operating conditions. The [ECM](#) processes these signals and decides the actions necessary to maintain optimum engine performance in terms of driveability, fuel efficiency and exhaust emissions. The memory of the [ECM](#) is programmed with instructions for how to control the engine, this known as the strategy. The memory also contains data in the form of maps which the [ECM](#) uses as a basis for fueling and emission control. By comparing the information from the sensors to the data in the maps, the [ECM](#) is able to calculate the various output requirements. The [ECM](#) contains an adaptive strategy which updates the system when components vary due to production tolerances or ageing.

The [ECM](#) receives a vehicle speed signal on a [CAN](#) bus connection from the [ABS](#) Module. Vehicle speed is an important input to the [ECM](#) strategies. The [ABS](#) derives the speed signal from the [ABS](#) wheel speed sensors. The frequency of this signal changes according to road speed. The [ECM](#) uses this signal to determine the following:

- How much to reduce engine torque during gear changes.
- When to permit speed control operation.
- To control the operation of the speed control system.
- Implementation of the idle strategy when the vehicle is stationary.

Camshaft Position Sensor (CMP)

E46902

The [CMP](#) is located on the front face of the left hand cylinder head. The sensor tip protrudes through the face to pick up on the reluctor behind the camshaft pulley. The [CMP](#) is a Hall effect type sensor

The [ECM](#) uses the [CMP](#) sensor signal to determine if the piston in No. 1 cylinder is at injection [TDC \(top dead center\)](#) or exhaust [TDC](#). Once this has been established, the [ECM](#) can then operate the correct injector to inject fuel into the cylinder when the piston is at injection [TDC](#).

The [CMP](#) sensor is a Hall effect sensor which used by the [ECM](#) at engine start-up to synchronize the [ECM](#) with the [CKP](#) sensor signal. The [ECM](#) does this by using the [CMP](#) sensor signal to identify number one cylinder to ensure the correct injector timing. Once the [ECM](#) has established the injector timing, the [CMP](#) sensor signal is no longer used.

The [CMP](#) sensor receives a 5V supply from the [ECM](#). Two further connections to the [ECM](#) provide ground and signal output.

If a fault occurs, an error is registered in the [ECM](#). Two types of failure can occur; camshaft signal frequency too high or total failure of the camshaft signal. The error recorded by the [ECM](#) can also relate to a total failure of the crankshaft signal or crankshaft signal dynamically implausible. Both components should be checked to determine the cause of the fault.

If a fault with the [CMP](#) sensor is running, the engine will continue to run but the [ECM](#) will deactivate boost pressure control. Once the engine is switched off, the engine will crank but will not restart while the fault is present.

Crankshaft Position Sensor (CKP)

E46903

The [CKP](#) sensor is located at the rear of the engine block on the left hand side. The sensor tip is aligned with a magnetic trigger which is attached to the crankshaft. The reluctor is a press fit on the end of the crankshaft. The trigger wheel must be carefully aligned to the crankshaft to ensure correct timing. The sensor produces a square wave signal, the frequency of which is proportional to engine speed.

The [ECM](#) monitors the [CKP](#) sensor signal and can detect engine over-speed. The [ECM](#) counteracts engine over-speed by gradually fading out speed synchronized functions. The [CKP](#) is a Hall effect sensor. The sensor measures the magnetic field variation induced by the magnetized trigger wheel.

The trigger wheel has two missing teeth representing 6° of crankshaft rotation. The two missing teeth provide a reference point for the angular position of the crankshaft.

When the space with the two missing teeth pass the sensor tip, a gap in the signal is produced which the [ECM](#) uses to determine the crankshaft position. The air gap between the sensor tip and the ring is important to ensure correct signals are output to the [ECM](#). The recommended air gap between the [CKP](#) and the trigger wheel is 0.4 mm- 1.5 mm.

The [ECM](#) uses the signal from the [CKP](#) sensor for the following functions:

- Synchronisation.
- Determine fuel injection timing.
- Enable the fuel pump relay circuit (after the priming period).
- Produce an engine speed signal which is broadcast on the [CAN](#) bus for use by other systems.

Mass Air Flow/Intake Air Temperature (MAF/IAT) Sensor

E46904

The [MAF/IAT](#) sensor is located on the inlet air duct directly after the air filter box. The sensor combines the two functions of a [MAF](#) sensor and an [IAT](#) sensor in one unit. The sensor is housed in a plastic molding which is connected between the intake manifold and the air intake pipe.

The [MAF](#) sensor works on the hot film principle. Two sensing elements are contained within a film. One element is maintained at ambient (air intake) temperature, e.g. 25°Celsius (77°F). The other element is heated to 200°Celsius (392°F) above the ambient temperature, e.g. 225°Celsius (437°F). Intake air entering the engine passes through the [MAF](#) sensor and has a cooling effect on the film. The [ECM](#) monitors the current required to maintain the 200°Celsius (392°F) differential between the two elements and uses the differential to provide a precise, non-linear, signal which equates to the volume of air being drawn into the engine.

The [MAF](#) sensor output is a digital signal proportional to the mass of the incoming air. The [ECM](#) uses this data, in conjunction with signals from other sensors and information from stored fueling maps, to determine the precise fuel quantity to be injected into the cylinders. The signal is also used as a feedback signal for the [EGR](#) system.

The [IAT](#) sensor incorporates a [NTC \(negative temperature coefficient\)](#) thermistor in a voltage divider circuit. The [NTC](#) thermistor works on the principle of decreasing resistance in the sensor as the temperature of the intake air increases. As the thermistor allows more current to pass to ground, the voltage sensed by the [ECM](#) decreases. The change in voltage is proportional to the temperature change of the intake air. Using the voltage output from the [IAT](#) sensor, the [ECM](#) can correct the fueling map for intake air temperature. The correction is an important requirement because hot air contains less oxygen than cold air for any given volume.

The [MAF](#) sensor receives a 12V supply from the [BJB](#) and a ground connection via the [ECM](#). Two further connections to the [ECM](#) provide a [MAF](#) signal and [IAT](#) signal.

The [IAT](#) sensor receives a 5V reference voltage from the [ECM](#) and shares a ground with the [MAF](#) sensor. The signal output from the [IAT](#) sensor is calculated by the [ECM](#) by monitoring changes in the supplied reference voltage to the [IAT](#) sensor voltage divider circuit.

The [ECM](#) checks the calculated air mass against the engine speed. If the calculated air mass is not plausible, the [ECM](#) uses a default air mass figure which is derived from the average engine speed compared to a stored characteristic map. The air mass value will be corrected

using values for boost pressure, atmospheric pressure and air temperature.

If the [MAF](#) sensor fails the [ECM](#) implements the default strategy based on engine speed. In the event of a [MAF](#) sensor signal failure, the following symptoms may be observed:

- [EGR](#) system off
- Delayed engine response
- Reduced engine performance.

If the [IAT](#) sensor fails the [ECM](#) uses a default intake air temperature of 40°Celsius (104°F). In the event of an [IAT](#) sensor failure, any of the following symptoms may be observed:

- Under fueling, resulting in reduced engine performance.

Engine Coolant Temperature sensor

E46905

The [ECT](#) is located in the top hose at the coolant manifold junction. The [ECT](#) sensor provides the [ECM](#) and the instrument cluster with engine coolant temperature status.

The [ECM](#) uses the temperature information for the following functions:

- Fueling calculations
- Limit engine operation if engine coolant temperature becomes too high
- Cooling fan operation
- Glow plug activation time.

The instrument cluster uses the temperature information for temperature gauge operation. The engine coolant temperature signal is also transmitted on the [CAN](#) bus by the instrument cluster for use by other systems.

The [ECM/ECT](#) sensor circuit consists of an internal voltage divider circuit which incorporates an [NTC](#) thermistor. As the coolant temperature rises the resistance through the sensor decreases and vice versa. The output from the sensor is the change in voltage as the thermistor allows more current to pass to earth relative to the temperature of the coolant.

The [ECM](#) compares the signal voltage to stored values and adjusts fuel delivery to ensure optimum driveability at all times. The engine will require more fuel when it is cold to overcome fuel condensing on the cold metal surfaces inside the combustion chamber. To achieve a richer air/fuel ratio, the [ECM](#) extends the injector opening time. As the engine warms up the air/fuel ratio is leaned off.

The input to the sensor is a 5V reference voltage supplied from the voltage divider circuit within the [ECM](#). The ground from the sensor is also connected to the [ECM](#) which measures the returned current and calculates a resistance figure for the sensor which relates to the coolant temperature.

The following table shows engine coolant temperature values and the corresponding sensor resistance and voltage values.

Coolant Temperature Sensor Response

Temperature (Degrees Celsius)	Resistance (Kohms)	Voltage (Volts)
-40	925	4.54
-30	496	4.46
-20	277	4.34
-10	160	4.15
0	96	3.88
10	59	3.52
20	37	3.09
30	24	2.62
40	16	2.15
50	11	1.72
60	7.5	1.34
70	5.6	1.04
80	3.8	0.79
90	2.9	0.64
100	2.08	0.49
110	1.56	0.38
120	1.19	0.29
130	0.918	0.22
140	0.673	0.17
150	0.563	0.14

If the [ECT](#) sensor fails, the following symptoms may be observed:

- Difficult cold start (under extreme conditions).
- Engine performance compromised.
- Temperature gauge inoperative or inaccurate reading.

In the event of [ECT](#) sensor signal failure, the [ECM](#) applies a default value of 80°Celsius (176°F) coolant temperature for fueling purposes. The [ECM](#) will also permanently operate the cooling fan at all times when the ignition is switched on, to protect the engine from overheating.

Engine Oil Temperature Sensor

E46906

The oil temperature sensor is located in the engine sump. The temperature sensor is a [NTC](#) type which operates in the -30 Degrees Celsius to +150 Degrees Celsius temperature range.

Oil Temperature Sensor Response

Temperature Degrees Celsius	Resistance Ohms
60	620
90	255
120	117
150	60

Fuel Rail Temperature Sensor

The fuel rail temperature sensor is located on the LP return line.

The sensor is an [NTC](#) sensor which is connected to the [ECM](#) by two wires. The [ECM](#) fuel temperature sensor circuit consists of an internal voltage divider circuit which incorporates an [NTC](#) thermistor. As the fuel temperature rises the resistance through the sensor decreases. The output from the sensor is the change in voltage as the thermistor allows more current to pass to earth relative to the temperature of the fuel.

The [ECM](#) monitors the fuel temperature constantly. If the fuel temperature exceeds 130°Celsius (185°F), the [ECM](#) invokes an engine 'derate' strategy. This reduces the amount of fuel delivered to the injectors in order to allow the fuel to cool. When this occurs, the driver may notice a loss of performance.

Further fuel cooling is available by a bi-metallic valve diverting fuel through the fuel cooler when the fuel reaches a predetermined temperature.

The wires to the fuel sensor are monitored by the [ECM](#) for short and open circuit. The [ECM](#) also monitors the 5V supply. If a failure occurs a fault is recorded in the [ECM](#) memory and the [ECM](#) uses a default fuel pressure value.

If the [ECM](#) registers an 'out of range' deviation between the pressure signal from the sensor and the pre-programmed 'set point' a fault is stored in the [ECM](#) memory. Depending on the extent of the deviation, the [ECM](#) will reduce the injection quantity, stop the engine immediately or prevent further engine starting.

Brake Light Switch

E46910

The brake switch is located on the brake pedal and is operated by the brake pedal. The switch has a normally open circuit switch which closes the circuit when the driver has applied the brakes. The switch is connected directly to the [ECM](#) and the [ECM](#) also receives a brake light signal on the [CAN](#) bus from the [ABS](#) control module.

The [ECM](#) uses the brake signal for the following:

- To limit fuelling during braking (only when adaptive speed control is active)
- To inhibit/cancel Speed control if the brakes are applied.

In the event of a brake switch failure, the following symptoms may be observed:

- Speed control inactive
- Increased fuel consumption.

Glow Plugs

E46912

Three glow plugs are located in each of the cylinder heads, on the inlet side. The glow plugs and the glow plug relay are a vital part of the engine starting strategy. The glow plugs heat the air inside the cylinder during cold starts to assist combustion. The use of glow plugs helps reduce the amount of additional fuel required on start-up, and consequently reduces the emission of black smoke. The use of glow plugs also reduces the amount of injection advance required, which reduces engine noise, particularly when idling with a cold engine.

There are three phases of glow plug activity:

- Pre-heat
- During crank
- Post heat

The main part of the glow plug is a tubular heating element which protrudes into the combustion chamber of the engine. The heating element contains a spiral filament encased in magnesium oxide powder. At the tip of the tubular heating element is the heater coil. Behind the heater coil, and connected in series, is a control coil. The control coil regulates the heater coil to ensure that it does not overheat.

Pre-heat is the length of time the glow plugs operate prior to engine cranking. The [ECM](#) controls the pre-heat time based on [ECT](#) sensor output and battery voltage. If the [ECT](#) sensor fails, the [ECM](#) will use the fuel temperature sensor value as a default value. The pre-heat duration is extended if the coolant temperature is low and the battery is not fully charged.

Post heat is the length of time the glow plugs operate after the engine starts. The [ECM](#) controls the post heating time based on [ECT](#) sensor output. The post heat phase reduces engine noise, improves idle quality and reduces hydrocarbon emissions.

At [ECT](#)s below 0 degrees celcius instrument cluster displays 'COLD START IN PROGRESS' in the message center. The glow-lamp is activated separately from the glow-plugs, so is not illuminated during or after start. The plugs can still be ON when the lamp is off in these two phases.

In the event of glow plug failure, the engine may be difficult to start.

Boost Air Temperature Sensor

E53446

The boost air temperature sensor is located in the rear of the intake chamber immediately preceding the electric throttle. The sensor is used to measure the intake air temperature from the turbo in order to calculate the required amount of fueling.

Boost Pressure Control

The Boost Pressure (BP) sensor is located post turbo after the electric throttle valve. The sensor provides a voltage signal to the [ECM](#) relative to the intake manifold pressure. The BP sensor has a three pin connector which is connected to the [ECM](#) and provides a 5V reference supply from the [ECM](#), a signal input to the [ECM](#) and a ground for the sensor.

The BP sensor uses diaphragm transducer to measure pressure. The [ECM](#) uses the BP sensor signal for the following functions:

- Maintain manifold boost pressure.
- Reduce exhaust smoke emissions when driving at high altitude.
- Control of the [EGR](#) system.

If the BP sensor fails, the [ECM](#) uses a default pressure of 1013 mbar (14 lbf/in²). In the event of a BP sensor failure, the following symptoms may be observed:

- Altitude compensation inoperative (black smoke emitted from the exhaust).
- Active boost control inoperative.

Boost control is achieved by the use of a direct drive electric actuator. The actuator is attached to the side of the turbo unit and is connected with the control mechanism via a linkage. The electric actuator works on the torque motor principal and has integrated control module.

The electric actuator moves the control vanes through an 60 degree stroke and has the capability to learn its own maximum stroke positions. The electric actuator is controlled via [PWM \(pulse width modulation\)](#) signals from the [ECM](#).

If the [ECM](#) detects a fault with the Boost Pressure (BP) sensor, it uses an open loop boost control based on engine speed and airflow as a default value.

Knock Sensors

E47296

The TDV6 EMS has two knock sensors located in the V of the engine, one per cylinder bank. The sensors are connected to the [ECM](#) via a twisted pair.

The knock sensors produce a voltage signal in proportion to the amount of mechanical vibration generated at each ignition point. Each sensor monitors the related cylinder bank.

The knock sensors incorporate a piezo-ceramic crystal. This crystal produces a voltage whenever an outside force tries to deflect it, (i.e. exerts a mechanical load on it). When the engine is running, the compression waves in the material of the cylinder block, caused by the combustion of the fuel/air mixture within the cylinders, deflect the crystal and produce an output voltage signal. The signals are supplied to the [ECM](#), which compares them with 'mapped' signals stored in memory. From this, the [ECM](#) can determine when detonation occurs on individual cylinders. When detonation is detected, the [ECM](#) retards the ignition timing on that cylinder for a number of engine cycles, then gradually returns it to the original setting.

Care must be taken at all times to avoid damaging the knock sensors, but particularly during removal and fitting procedures. The recommendations regarding torque and surface preparation must be adhered to. The torque applied to the sensor and the quality of the surface preparation both have an influence over the transfer of mechanical noise from the cylinder block to the crystal.

The [ECM](#) uses the signals supplied by the knock sensors, in conjunction with the signal it receives from the camshaft sensor, to determine the optimum ignition point for each cylinder. The ignition point is set according to preprogrammed ignition maps stored within the [ECM](#). If the only fuel available is of poor quality, or the customer switches to a lower grade of fuel after using a high grade for a period of time, the engine may suffer slight pre-ignition for a short period. This amount of pre-ignition will not damage the engine. This situation will be evident while the [ECM](#) learns and then modifies its internal mapping to compensate for the variation in fuel quality. This feature is called adaption. The [ECM](#) has the capability of adapting its fuel and ignition control outputs in response to several sensor inputs.

The [ECM](#) will cancel closed loop control of the ignition system if the signal received from either knock sensor becomes implausible. In these circumstances the [ECM](#) will default to a safe ignition map. This measure ensures the engine will not become damaged if low quality fuel is used. The [MIL \(malfunction indicator lamp\)](#) will not illuminate, although the driver may notice that the engine 'pinks' in some driving conditions and displays a drop in performance and smoothness.

When a knock sensor fault is stored, the [ECM](#) will also store details of the engine speed, engine load and the coolant temperature.

Fuel Rail Pressure Control Valve

E46984

Item Description

1	Fuel volume control valve
2	High pressure fuel pump
3	Fuel rail pressure control valve

The fuel rail pressure control valve is incorporated into the high pressure fuel pump. The control valve regulates the fuel pressure within the fuel rail and is controlled by the [ECM](#). The control valve is a [PWM](#) controlled solenoid valve.

When the solenoid is de-energized, an internal spring holds an internal valve closed. At fuel pressure of 100 bar (1450 lbf/in²) or higher, the force of the spring is overcome, opening the valve and allowing fuel pressure to decay into the fuel return pipe. When the pressure in the fuel rail decays to approximately 100 bar (1450 lbf/in²) or less, the spring force overcomes the fuel pressure and closes the valve. When the [ECM](#) energizes the solenoid, the valve is closed allowing the fuel pressure to build. The pressure in the fuel rail in this condition can reach approximately 1600 bar.

The [ECM](#) controls the fuel rail pressure by operating the control valve solenoid using a [PWM](#) signal. By varying the duty cycle of the [PWM](#) signal, the [ECM](#) can accurately control the fuel rail pressure and hence the pressure delivered to the injectors according to engine load. This is achieved by the control valve allowing a greater or lesser volume of fuel to pass from the high pressure side of the pump to the un-pressurized fuel return line, regulating the pressure on the high pressure side.

The fuel rail pressure control valve receives a [PWM](#) signal from the [ECM](#) of between 0 and 12V. The [ECM](#) controls the operation of the control valve using the following information to determine the required fuel pressure:

- Fuel rail pressure
- Engine load
- Accelerator pedal position
- Engine temperature
- Engine speed.

In the event of a total failure of the fuel rail pressure control valve, the engine will not start.

In the event of a partial failure of the fuel rail pressure control valve, the [ECM](#) will activate the solenoid with the minimum duty cycle which results in the injection quantity being limited.

Fuel Volume Control Valve

The fuel rail volume control valve is incorporated into the high pressure fuel pump. The VCV spills unwanted fuel back to the tank (or LP system) or forwards it to the PCV. This avoids unused fuel being pressurized by the HP stage of the pump, only to be spilt back to LP by the PCV wasting energy and heating the fuel.

Injectors

There are six electronic fuel injectors located in a central position between the four valves of each cylinder. The [ECM](#) divides the injectors into two banks of three with cylinders 1 to 3 being designated bank A and cylinders 4 to 6 designated bank B, with injector numbers 1 and 4 at the front of the engine.

Each injector is supplied with pressurized fuel from the fuel rail and delivers finely atomized fuel directly into the combustion chambers. Each injector is individually controlled by the [ECM](#) which operates each injector in the firing order and controls the injector opening period via [PWM](#) signals. Each injector receives a 120V supply from the [ECM](#) and, using programmed injection/timing maps and sensor signals, determines the precise pilot and main injector timing for each cylinder. If battery voltage falls to between 6 and 9V, fuel injector operation is restricted, affecting emissions, engine speed range and idle speed. In the event of a failure of a fuel injector, the following symptoms may be observed:

- Engine misfire
- Idle irregular
- Reduced engine performance
- Reduced fuel economy
- Difficult starting
- Increased smoke emissions.

The [ECM](#) monitors the wires for each injector for short circuit and open circuit, each injector and the transient current within the [ECM](#). If a defect is found, an error is registered in the [ECM](#) for the injector in question.

EGR System

The [EGR](#) system comprises:

- [EGR](#) modulator x 2
- [EGR](#) cooler x 2
- Associated connecting pipes

EGR Modulator and Cooler

E46914

The combined [EGR](#) modulator and cooler is located under each cylinder bank, between the exhaust manifold and the cylinder head. The cooler side of the [EGR](#) is connected to the vehicle cooling system via hoses. The inlet exhaust side is connected directly into the exhaust

manifolds on each side. The exhaust gas passes through the cooler and is expelled via the actuator and a metal pipe into the throttle housing. The [EGR](#) modulator is a solenoid operated valve which is controlled by the [ECM](#). The [ECM](#) uses the [EGR](#) modulator to control the amount of exhaust gas being re-circulated in order to reduce exhaust emissions and combustion noise.

The [EGR](#) modulator is controlled by an H bridge driver to control the precise amount of exhaust gas delivered to the cylinders.

The modulators are operated through their full range at each engine shut down, to clear any carbon deposits that may have built up whilst the engine was running

In the event of a failure of the [EGR](#) modulator, the [EGR](#) function will become inoperative. The [ECM](#) can monitor the [EGR](#) modulator solenoid for short circuits and store fault codes in the event of failure. The modulator can also be activated for testing using the Jaguar recommended diagnostic equipment.

Accelerator Pedal Position Sensor (APP)

The [APP](#) is incorporated into the pedal assembly. The sensor is a twin track rotary potentiometer type.

The [APP](#) sensor is located in plastic housing which is integral with the throttle pedal. The housing is injection molded and provides location for the [APP](#) sensor. The sensor is mounted externally on the housing and is secured with two Torx screws. The external body of the sensor has a six pin connector which accepts a connector on the vehicle wiring harness.

The sensor has a spigot which protrudes into the housing and provides the pivot point for the pedal mechanism. The spigot has a slot which allows for a pin, which is attached to the sensor potentiometers, to rotate through approximately 90°, which relates to pedal movement. The pedal is connected via a link to a drum, which engages with the sensor pin, changing the linear movement of the pedal into rotary movement of the drum. The drum has two steel cables attached to it. The cables are secured to two tension springs which are secured in the opposite end of the housing. The springs provide 'feel' on the pedal movement and require an effort from the driver similar to that of a cable controlled throttle. A detente mechanism is located at the forward end of the housing and is operated by a ball located on the drum. At near maximum throttle pedal movement, the ball contacts the detente mechanism. A spring in the mechanism is compressed and gives the driver the feeling of depressing a 'kickdown' switch when full pedal travel is achieved.

Electronic Throttle

E46900

The electric throttle body is located in the inlet tract prior to where the inlet splits to divert air flow into the two separate air intake manifolds. The electric throttle controls the volume of air allowed into the inlet manifold by means of a DC motor which controls a flap in the body of the throttle. This is done in response to inputs from the engine management system.

Just after the throttle flap the tubes from the [EGR](#) valves/coolers are joined into the assembly.

Central Junction Box

E47607

The [CJB](#) initiates the power up and power down routines within the [ECM](#). When the ignition is turned on 12V is applied to the Ignition Sense input. The [ECM](#) then starts its power up routines and turns on the [ECM](#) main relay; the main power to the [ECM](#) and it's associated system components. When the ignition is turned OFF the [ECM](#) will maintain its powered up state for up to 60 seconds while it initiates its power down routine and on completion will turn off the [ECM](#) main relay.

Generator

E47591

The generator has a multifunction voltage regulator for use in a 14V charging system with 6÷12 zener diode bridge rectifiers.

The [ECM](#) monitors the load on the electrical system via [PWM](#) signal and adjusts the generator output to match the required load. The [ECM](#) also monitors the battery temperature to determine the generator regulator set point. This characteristic is necessary to protect the battery; at low temperatures battery charge acceptance is very poor so the voltage needs to be high to maximize any rechargeability, but at high temperatures the charge voltage must be restricted to prevent excessive gassing of the battery with consequent water loss.

The generator has a smart charge capability that will reduce the electrical load on the generator reducing torque requirements, this is implemented to utilize the engine torque for other purposes. This is achieved by monitoring three signals to the [ECM](#):

- Generator sense (A sense), measures the battery voltage at the [CJB](#).
- Generator communication (Alt Com) communicates desired generator voltage set point from [ECM](#) to generator.
- Generator monitor (Alt Mon) communicates the extent of generator current draw to [ECM](#). This signal also transmits faults to the [ECM](#) which will then sends a message to the instrument cluster on the [CAN](#) bus to illuminate the charge warning lamp.

DPF Temperature Sensors

Three temperature sensors are used in the DPF system. One is located before the catalytic convertor, the second sensor is after the catalytic converter and the third sensor is located before the DPF.

The sensors measure the temperature of exhaust gas exiting the turbocharger, before it passes through the DPF and after it has passed through the DPF and provides the information required by the [ECM](#) to calculate the DPF temperature. The information is used, in conjunction with other data, to estimate the amount of accumulated particulate and to control the DPF temperature.

The sensors are Negative Temperature Co-efficient (NTC) type resistors, which measure the temperature of the exhaust gases. The resistance, and subsequently the voltage at the sensor will decrease as the exhaust gas temperature increases.

In the event of a fault in a temperature sensor, the [ECM](#) uses a substitute value of 350°C (1202°F).

Differential Pressure Sensor

The differential pressure sensor is used by the DPF software to monitor the condition of the DPF. Two pipe connections on the sensor are connected by pipes to the inlet and outlet ends of the DPF. The pipes allow the sensor to measure the inlet and outlet pressures of the DPF.

As the amount of particulates trapped by the DPF increases, the pressure at the inlet side of the DPF increases in comparison to the DPF outlet. The DPF software uses this comparison, in conduction with other data, to calculate the accumulated amount of trapped particulates.

By measuring the pressure difference between the DPF inlet and outlet air flow and the DPF temperature, the DPF software can determine if the DPF is becoming blocked and requires regeneration.

A DPF is recognized as overloaded if the differential pressure under certain operating conditions exceeds the overload limit calculated by the [ECM](#). The DPF software may start regeneration attempts but be unable to complete them. These attempts are counted by the [ECM](#) and, if the maximum number of regeneration attempts is reached, a fault entry is recorded in the [ECM](#) at the next ignition on cycle.

The DPF software performs the following checks using the DPF differential pressure sensor:

- Plausibility check
- Diesel particulate filter efficiency
- Diesel particulate filter overloaded
- Diesel particulate filter clogged
- Monitoring of the maximum regeneration attempts in the lower load range.

Electronic Engine Controls - TDV6 2.7L Diesel - Electronic Engine Controls

Diagnosis and Testing

Principles of Operation

For a detailed description of the 2.7L Diesel electronic engine controls, refer to the relevant Description and Operation section in the workshop manual. REFER to: (303-14 Electronic Engine Controls - 2.7L Diesel)

Electronic Engine Controls (Description and Operation),
 Electronic Engine Controls (Description and Operation),
 Electronic Engine Controls (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Engine oil level ● Cooling system coolant level ● Fuel level ● Fuel contamination ● Fuel leaks ● Front End Accessory Drive (FEAD) belt 	<ul style="list-style-type: none"> ● Fuses ● Wiring harness ● Electrical connector(s) ● Sensor(s) ● Engine control module (ECM) ● Transmission control module (TCM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

• NOTE: If the module or a component is suspect and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

Symptom	Possible source	Action
Engine cranks, but does not start	<ul style="list-style-type: none"> ● Low/contaminated fuel ● Air leakage ● Fuel system low pressure circuit fault ● Fuel pump module fault ● Blocked fuel filter ● Fuel volume control valve (FVCV) blocked/contaminated ● Fuel pressure control valve (FPCV) blocked/contaminated ● Fuel injection pump failure ● Crankshaft position (CKP) sensor ● ECM fault 	Check the fuel level/condition. Check the integrity of the air intake system and for correct installation. Check the fuel pump module operation, check the fuel system low pressure circuit for leaks/damage. Check the fuel filter, check the FVCV and FPCV. Check the fuel injection pump. Check the CKP sensor and circuits. Refer to the new module/component installation note at the top of the Symptom Chart if an ECM is suspect
Difficult to start	<ul style="list-style-type: none"> ● Glow plug system fault (very cold conditions) ● Low/contaminated fuel ● Air leakage ● Fuel pump module fault ● Fuel system low pressure circuit fault ● Blocked fuel filter ● Fuel volume control valve (FVCV) blocked/contaminated ● Fuel pressure control valve (FPCV) blocked/contaminated ● Exhaust gas recirculation (EGR) valve(s) fault 	Check the glow plugs and circuits. Check the fuel level/condition. Check the integrity of the air intake system and for correct installation. Check the fuel pump module operation, check the fuel system low pressure circuit for leaks/damage. Check the fuel filter, FVCV and FPCV. Check the EGR system
Rough idle	<ul style="list-style-type: none"> ● Air ingress ● Low/contaminated fuel ● Fuel system low pressure circuit fault ● Blocked fuel filter ● Fuel volume control valve (FVCV) blocked/contaminated ● Fuel pressure control valve (FPCV) 	Check the integrity of the air intake system and for correct installation. Check the fuel level/condition. Check the fuel system low pressure circuit for leaks/damage. Check the fuel filter, FVCV and FPCV. Check the EGR system

Symptom	Possible source	Action
	<ul style="list-style-type: none"> blocked/contaminated ● Exhaust gas recirculation (EGR) valve(s) fault 	
Lack of power when accelerating	<ul style="list-style-type: none"> ● Air intake system fault ● Diesel particulate filter (DPF) blocked/restricted ● Restricted exhaust system ● Low fuel pressure ● Exhaust gas recirculation (EGR) valve(s) fault ● Variable geometry turbocharger (VGT) actuator fault 	Check the integrity of the air intake system and for correct installation. Check for a blocked DPF or catalytic converter, install new components as required. Check the fuel pressure. Check the EGR system. Check the VGT actuators
Engine stops/stalls	<ul style="list-style-type: none"> ● Low/contaminated fuel ● Air ingress ● Fuel system low pressure circuit fault ● Fuel volume control valve (FVCV) blocked/contaminated ● Fuel pressure control valve (FPCV) blocked/contaminated ● High pressure fuel leak ● Exhaust gas recirculation (EGR) valve(s) fault 	Check the fuel level/condition. Check the fuel system low pressure circuit for leaks/damage. Check for fuel system leaks, FVCV and FPCV. Check the EGR system
Engine judders	<ul style="list-style-type: none"> ● Low/contaminated fuel ● Air ingress ● Fuel system low pressure circuit fault ● Fuel metering valve blocked/contaminated ● Fuel volume control valve (FVCV) blocked/contaminated ● Fuel pressure control valve (FPCV) blocked/contaminated ● High pressure fuel leak ● Fuel injection pump fault 	Check the fuel level/condition. Check the fuel system low pressure circuit for leaks/damage. Check for fuel system leaks, FVCV and FPCV. Check the fuel injection pump
Excessive fuel consumption	<ul style="list-style-type: none"> ● Fuel system low pressure circuit fault ● Fuel volume control valve (FVCV) blocked/contaminated ● Fuel pressure control valve (FPCV) blocked/contaminated ● Fuel temperature sensor leak ● High pressure fuel leak ● Injector(s) failure ● Exhaust gas recirculation (EGR) valve(s) fault 	Check the fuel system low pressure circuit for leaks/damage. Check the FVCV and FPCV. Check the fuel temperature sensor, fuel injection pump, etc for leaks. Check for injector DTCs. Check the EGR system

DTC index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

- NOTE: If the module or a component is suspect and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).
- NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B10A231	Crash Input	<ul style="list-style-type: none"> ● RCM PWM signal circuit - no signal 	Refer to the electrical circuit diagrams and check RCM PWM signal circuit for short, open circuit
B10A236	Crash Input	<ul style="list-style-type: none"> ● Signal frequency too low 	Check RCM for related DTCs and refer to the relevant DTC Index
B10A237	Crash Input	<ul style="list-style-type: none"> ● Signal frequency too high 	Check RCM for related DTCs and refer to the relevant DTC Index

DTC	Description	Possible Cause	Action
B10A239	Crash Input	<ul style="list-style-type: none"> Incorrect has too few pulses 	Check RCM for related DTCs and refer to the relevant DTC Index
B10A23A	Crash Input	<ul style="list-style-type: none"> Incorrect has too many pulses 	Check RCM for related DTCs and refer to the relevant DTC Index
B11D901	Battery Voltage	<ul style="list-style-type: none"> General electrical failure 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Check battery is in fully charged and serviceable condition, refer to the battery care manual
B11DB01	Battery Monitoring Module	<ul style="list-style-type: none"> Battery monitoring system hardware fault 	Disconnect vehicle battery, re-connect after 60 seconds, clear DTC and retest. If DTC remains install a new battery monitoring module
B11DB87	Battery Monitoring Module	<ul style="list-style-type: none"> Battery monitoring module connector dis-connected/poor connection Battery monitoring module to RJB LIN circuit - open circuit Battery monitoring module to battery positive monitor circuit - open circuit Battery monitoring module/RJB failure 	If additional DTCs B108783, B108786, B108787 are logged, suspect the RJB. Check and install a new RJB as required, refer to the new module/component installation note at the top of the DTC Index. If additional DTCs B108783, B108786, B108787 are NOT logged, check for good/clean contact at battery monitoring module connector, refer to electrical circuit diagrams and check battery monitoring module to RJB LIN circuit and battery monitoring module to battery positive monitor circuit for open circuit. Clear DTC and repeat automated diagnostic procedure using manufacturer approved diagnostic system. If DTC remains suspect the battery monitoring module, check and install a new battery monitoring module as required, refer to the new module/component installation note at the top of the DTC Index
B120668	Crash Occurred	<ul style="list-style-type: none"> ECU has detected the vehicle has crashed - Event information DTC only 	Check RCM and RJB for related DTCs and refer to the relevant DTC Index
P000113	Fuel Volume Regulator Control Circuit/Open	<ul style="list-style-type: none"> Fuel volume regulator control circuit - open circuit Fuel volume regulator control valve failure 	Refer to the electrical circuit diagrams and check fuel volume regulator control circuit for open circuit. Check resistance across fuel regulator control valve is between 1.5 and 15 Ohms, install a new valve as required
P000200	Fuel Volume Regulator Control Circuit Range/Performance	<ul style="list-style-type: none"> Fuel volume regulator control circuit - short to ground, power, high resistance Fuel volume regulator control valve failure ECM failure 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check fuel volume regulator control circuit for short to ground, power, high resistance. Check and install new fuel volume regulator control valve/ECM as required, refer to the new module/component installation note at the top of the DTC Index
P000311	Fuel Volume Regulator Control Circuit Low	<ul style="list-style-type: none"> Fuel volume regulator control circuit - short to ground Fuel volume regulator control valve failure 	Refer to the electrical circuit diagrams and check fuel volume regulator control circuit for short to ground. Check resistance across fuel regulator control valve is between 1.5 and 15 Ohms, install a new valve as required
P000319	Fuel Volume Regulator Control Circuit Low	<ul style="list-style-type: none"> Fuel volume regulator control circuit - current above threshold Fuel volume regulator control valve failure 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check turbocharger boost control solenoid A circuit for short to ground. Suspect the turbocharger boost control solenoid A, check and install a new turbocharger as required, refer to the new module/component installation note at the top of the DTC Index
P004812	Turbocharger/Supercharger Boost Control Solenoid A Circuit High	<ul style="list-style-type: none"> Turbocharger boost control solenoid A circuit - short to power Turbocharger boost control solenoid A failure 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check turbocharger boost control solenoid A circuit for short to power. Suspect the turbocharger boost control solenoid A, check and install a new turbocharger as required, refer to the new module/component installation note at the top of the DTC Index
P004C00	Turbocharger/Supercharger Boost Control Solenoid B Circuit Low	<ul style="list-style-type: none"> Turbocharger boost control solenoid B circuit - short to ground Turbocharger boost control solenoid B failure 	Refer to the electrical circuit diagrams and check turbocharger boost control solenoid B circuit for short to ground. Suspect the turbocharger boost control solenoid B, check and install a new turbocharger as required, refer to the new module/component installation note at the top of the DTC Index

Electronic Engine Controls - TDV6 2.7L Diesel - Camshaft Position (CMP) Sensor

Removal and Installation

Removal

- NOTE: Removal steps in this procedure may contain installation details.

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the LH exhaust gas recirculation (EGR) valve.
For additional information, refer to: [Exhaust Gas Recirculation \(EGR\) Valve LH](#) (303-08A Engine Emission Control - TDV6 2.7L Diesel, Removal and Installation).
3. Disconnect the camshaft position (CMP) sensor electrical connector.

4. Remove the CMP sensor.

Installation

1. NOTE: Only turn the engine in the normal direction of rotation.
- NOTE: Timing belt left hand cover shown removed for clarity.

Turn the engine until one of the three webs on the back of the camshaft pulley is visible through the CMP sensor housing.

2.  **CAUTION:** The CMP sensor tip must rest on one of the three webs on the back of the camshaft pulley. Incorrect installation may result in the CMP sensor being damaged.

• **NOTE:** Timing belt left hand cover shown removed for clarity.

Install the CMP sensor until the tip of the sensor touches the back of the camshaft pulley.

3. Install the CMP sensor retaining bolt.

- Tighten to 10 Nm.

4. Connect the CMP sensor electrical connector.

5. Install the LH EGR valve.

For additional information, refer to: [Exhaust Gas Recirculation \(EGR\) Valve LH](#) (303-08A Engine Emission Control - TDV6 2.7L Diesel, Removal and Installation).

6. Connect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

Electronic Engine Controls - TDV6 2.7L Diesel - Crankshaft Position (CKP) Sensor

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

2.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

3. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
4. Make sure the alignment mark, on the steering gear pinion seal protection cover, is central to the steering gear pinion casting.

E42703

VUJ0002958

5. Remove the steering gear shaft pinch bolt.

E31036

6. Detach the steering gear.

7. Secure the steering gear.

E 31035

8. Disconnect the power steering control valve actuator electrical connector.

E 49770

9. Disconnect the crankshaft position (CKP) sensor electrical connector.

E 52427

10. Remove the CKP sensor blanking cover.

E 52428

11. NOTE: The CKP sensor retaining bolt should not be removed from the CKP sensor.

Fully loosen the CKP sensor retaining bolt.

E 52429

12. Remove the CKP sensor.

Installation

1.  CAUTION: Install the CKP sensor correctly into the housing. Failure to follow this instruction may result in damage to the CKP sensor.

To install, reverse the removal procedure.

2. Tighten to 5 Nm.

3. Tighten to 100 Nm.

4. Tighten to 35 Nm.

Electronic Engine Controls - TDV6 2.7L Diesel - Crankshaft Position (CKP) Sensor Ring

Removal and Installation

Special Tool(s)

Installer - Crankshaft Position (CKP) Sensor Ring

303-1130

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.
3. Remove the flexplate.
For additional information, refer to: [Flexplate](#) (303-01A Engine - TDV6 2.7L Diesel, Removal and Installation).
4. Disconnect the crankshaft position (CKP) sensor electrical connector.

5. Remove the CKP sensor blanking cover.

6. **NOTE:** The CKP sensor retaining bolt should not be removed from the CKP sensor.

Fully loosen the CKP sensor retaining bolt.

7. Remove the CKP sensor.

8. Remove and discard the CKP sensor ring.

Installation

1. Install a new CKP sensor ring to the special tool.

- Make sure that the CKP sensor ring is aligned correctly with the special tool pip and that both mating surfaces are fully seated.

2. Install the special tool to the crankshaft.

- Align the special tool alignment peg to the timing hole on the crankshaft.

3. Install a new CKP sensor ring.

- Tighten the special tool nut, to install the CKP sensor ring to the crankshaft.

4. Loosen the special tool nut.

5. Remove the special tool.

6.  **CAUTION:** Install the CKP sensor correctly into the housing. Failure to follow this instruction may result in damage to the CKP sensor.

Install the CKP sensor.

- Tighten to 5 Nm.

7. Install the CKP sensor blanking cover

8. Connect the CKP sensor electrical connector.

9. Install the flexplate.

For additional information, refer to: [Flexplate](#) (303-01A Engine - TDV6 2.7L Diesel, Removal and Installation).

10. Connect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

Electronic Engine Controls - TDV6 2.7L Diesel - Engine Control Module (ECM)

Removal and Installation

Removal

All vehicles

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the cowl vent screen.
For additional information, refer to: [Cowl Vent Screen](#) (501-02 Front End Body Panels, Removal and Installation).

Right-hand drive vehicles

3. Remove the secondary bulkhead LH panel.
For additional information, refer to: [Secondary Bulkhead Panel LH - V8 4.2L Petrol/V8 S/C 4.2L Petrol/V6 3.0L Petrol/TDV6 2.7L Diesel](#) (501-02 Front End Body Panels, Removal and Installation).

Left-hand drive vehicles

4. Remove the secondary bulkhead RH panel.
For additional information, refer to: [Secondary Bulkhead Panel RH - V8 4.2L Petrol/V8 S/C 4.2L Petrol/V6 3.0L Petrol/TDV6 2.7L Diesel](#) (501-02 Front End Body Panels, Removal and Installation).

All vehicles

5. Remove the engine compartment brace.

6. NOTE: Left-hand shown, right-hand similar.

Remove the pedestrian protection actuator.

7. NOTE: Left-hand shown, right-hand similar.

Release the pedestrian protection actuator bracket.

8. NOTE: Left-hand shown, right-hand similar.

Reposition the pedestrian protection actuator bracket.

9. NOTE: Left-hand shown, right-hand similar.

Remove the engine control module (ECM) cover.

10. NOTE: Left-hand shown, right-hand similar.

Disconnect the 3 electrical connectors from the engine control module (ECM).

11. NOTE: Left-hand shown, right-hand similar.

Remove the ECM.

Installation

1. Install is the reverse of removal.

- Tighten to 10 Nm.

2. Tighten to 6 Nm.

E30422

3. Tighten to 25 Nm.

E98882

4. Tighten to 8 Nm.

E98881

5. Tighten to 25 Nm.

Electronic Engine Controls - TDV6 2.7L Diesel - Engine Coolant Temperature (ECT) Sensor

Sensor

Removal and Installation

Removal

CAUTION: Since injury such as scalding could be caused by escaping steam or coolant, make sure the vehicle cooling system is cool prior to carrying out this procedure

• **NOTE:** Removal steps in this procedure may contain installation details.

1. Remove the engine cover.
For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel \(501-05 Interior Trim and Ornamentation, Removal and Installation\)](#).
2. Disconnect the electrical connector.

3. CAUTIONS:

Be prepared to collect escaping fluids.

The seal is to be reused unless damaged.

Remove the engine coolant temperature (ECT) sensor.

- Lift the tang and rotate the ECT sensor anti-clockwise.

Installation

1. **NOTE:** Make sure that all the component mating faces are clean.

To install, reverse the removal procedure.

2. Fill the cooling system, keeping coolant to the upper level mark of the expansion tank.

Electronic Engine Controls - TDV6 2.7L Diesel - Engine Oil Pressure (EOP) Sensor

Removal and Installation

Removal

1. Remove the engine cover.
For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
2. Disconnect the engine oil pressure (EOP) sensor electrical connector.

E52407

3. Remove the EOP sensor.

E52406

Installation

1. To install, reverse the removal procedure.
 - Tighten to 15 Nm.

E52406

Electronic Engine Controls - TDV6 2.7L Diesel - Fuel Rail Pressure (FRP) Sensor

Removal and Installation

General Equipment

Pneumatic vacuum gun

Removal

• WARNINGS:

 Wait at least 30 seconds after the engine stops before commencing any repair to the high-pressure fuel injection system. Failure to follow this instruction may result in personal injury.

 Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

 The spilling of fuel is unavoidable during this operation. Ensure that all necessary precautions are taken to prevent fire and explosion.

 Do not carry out any repairs to the fuel system with the engine running. The fuel pressure within the system can be as high as 1650 bar (23,931 lb-sq-in). Failure to follow this instruction may result in personal injury.

• CAUTIONS:

 Make sure the workshop area in which the vehicle is being worked on is as clean and as dust free as possible. Foreign matter from work on clutches, brakes or from machining or welding operations can contaminate the fuel system and may result in later malfunction.

 Always carry out the cleaning process before carrying out any repairs to the fuel injection system components. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

 Diesel fuel injection equipment is manufactured to very precise tolerances and fine clearances. It is therefore essential that absolute cleanliness is observed when working with these components. Always install blanking plugs to any open orifices or lines. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

 Do not remove the fuel rail pressure sensor from the fuel injection diverter rail.

1. NOTE: If a new fuel rail pressure sensor is to be installed, a new fuel injection diverter rail and fuel rail pressure sensor must be installed as an assembly.

Disconnect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

2. Remove the engine cover.

For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).

3. Remove the secondary bulkhead center panel.

For additional information, refer to: [Secondary Bulkhead Center Panel](#) (501-02 Front End Body Panels, Removal and Installation).

4. Remove the cover from the engine wiring harness casing.

5. Remove the engine wiring harness casing.

6. Remove the injector sound proofing.

7. Disconnect the low pressure fuel inlet and return lines.

- Install suitable blanking caps to the fuel lines and unions.

8. Detach the engine wiring harness retaining bracket.

9. NOTE: Left-hand shown, right-hand similar.

Detach the high-pressure fuel supply lines.

10.  CAUTION: Make sure that the high-pressure fuel supply line remains in contact with the fuel injection supply manifold and the fuel injection diverter rail until both unions have been detached and cleaned. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

• NOTE: Left-hand shown, right-hand similar.

Loosen the high-pressure fuel supply lines.

11. Remove and discard the high-pressure fuel supply lines.

- Install blanking caps to the exposed ports.

12.  CAUTION: Make sure that the high-pressure fuel supply line remains in contact with the fuel injection supply manifold and the fuel injection diverter rail until both unions have been detached and cleaned. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

Remove and discard the high-pressure fuel diverter rail supply line.

- Install blanking caps to the exposed ports.

13. Remove the fuel line retaining nut.

14. Disconnect the fuel rail pressure (FRP) sensor electrical connector.

- Release the fuel charging wiring harness.

15. Reposition the fuel line.

16. Remove the FRP and fuel injection diverter rail assembly.

- Remove the 2 studs.

Installation

1. WARNINGS:

 Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

 Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

 Do not carry out any repairs to the fuel system with the engine running. The fuel pressure within the system can be as high as 1650 bar (23,931 lb-sq-in). Failure to follow this instruction may result in personal injury.

 This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

• CAUTIONS:

 Make sure the workshop area in which the vehicle is being worked on is as clean and as dust free as possible. Foreign matter from work on clutches, brakes or from machining or welding operations can contaminate the fuel system and may result in later malfunction.

 Always carry out the cleaning process before carrying out any repairs to the fuel injection system components. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

 Diesel fuel injection equipment is manufactured to very precise tolerances and fine clearances. It is therefore essential that absolute cleanliness is observed when working with these components. Always install blanking plugs to any open orifices or lines. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

 Do not remove the fuel rail pressure sensor from the fuel injection diverter rail.

Install the FRP and fuel injection diverter rail assembly.

- Install the two retaining studs, but do not fully tighten at this stage.

2. Attach the fuel line.

3. Connect the FRP sensor electrical connector.

4. Install the fuel line retaining nut.

- Tighten to 7 Nm.

5. Install a new high-pressure fuel supply line.

- Remove the blanking caps from the ports.
- Install the new high-pressure fuel supply line, tighten the fuel supply line unions finger tight.
- Tighten the fuel injection diverter rail retaining studs to 23 Nm.
- Tighten the high-pressure fuel supply line in the shown sequence.
- Stage 1: Tighten the high-pressure fuel supply line union at the fuel injection pump to 15 Nm.
- Stage 2: Tighten the high-pressure fuel supply line union at the fuel injection diverter rail to 15 Nm.
- Stage 3: Tighten the high-pressure fuel supply line union at the fuel injection pump to 30 Nm.
- Stage 4: Tighten the high-pressure fuel supply line union at the fuel injection diverter rail to 30 Nm.

6. NOTE: Left-hand shown, right-hand similar.

Install the new high-pressure fuel rail supply line.

- Remove the blanking caps from the ports.
- Install the new high-pressure fuel supply line, tighten the fuel supply line unions finger tight.
- Tighten the high-pressure fuel supply line in the shown sequence.
- Stage 1: Tighten the high-pressure fuel supply line union at the fuel injection diverter rail to 15 Nm.
- Stage 2: Tighten the high-pressure fuel supply line union at the fuel injection rail to 15 Nm.
- Stage 3: Tighten the high-pressure fuel supply line union at the fuel injection diverter rail to 30 Nm.
- Stage 4: Tighten the high-pressure fuel supply line union at the fuel injection rail to 30 Nm.

7. NOTE: Left-hand shown, right-hand similar.

Attach the high-pressure fuel supply lines.

- Tighten to 10 Nm.

8. Attach the engine wiring harness.

- Tighten to 7 Nm.

9. Attach the low-pressure fuel line.

- Remove the blanking caps from the ports.

10. Install the injector sound proofing.

11. Install the engine wiring harness casing.

12. Install the engine wiring harness cover.

- 13.** Install the secondary bulkhead center panel.
For additional information, refer to: [Secondary Bulkhead Center Panel](#) (501-02 Front End Body Panels, Removal and Installation).
- 14.** Install the engine cover.
For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
- 15.** Connect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
- 16.** Bleed the fuel system.

Electronic Engine Controls - TDV6 2.7L Diesel - Fuel Temperature Sensor

Removal and Installation

Removal

 **WARNING:** This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

 **CAUTION:** Diesel fuel injection equipment is manufactured to very precise tolerances and fine clearances. It is therefore essential that absolute cleanliness is observed when working with these components. Always install blanking plugs to any open orifices or lines. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

1. WARNINGS:

 Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

 Do not carry out any repairs to the fuel system with the engine running. The fuel pressure within the system can be as high as 1650 bar (23,931 lb-sq-in). Failure to follow this instruction may result in personal injury.

 **CAUTION:** Make sure the workshop area in which the vehicle is being worked on is as clean and as dust free as possible. Foreign matter from work on clutches, brakes or from machining or welding operations can contaminate the fuel system and may result in later malfunction.

Disconnect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

2. Remove the intake air shutoff throttle.

For additional information, refer to: [Intake Air Shutoff Throttle](#) (303-04A Fuel Charging and Controls - TDV6 2.7L Diesel, Removal and Installation).

3. Remove the injector sound proofing.

4. Disconnect the electrical connector.

E52415

5. Disconnect the fuel return line from the fuel cooler.

E100923

6. NOTE: Left-hand shown, right-hand similar.

Release the engine wiring harness from the fuel supply manifolds.

- Release and reposition the wiring harness.

7. Disconnect the engine oil pressure (EOP) switch electrical connector.

8. NOTE: Left-hand shown, right-hand similar.

Remove and discard the fuel injector leak off pipe retaining clips.

- Disconnect the fuel injector leak off pipe.

9. Remove the fuel injector leak off pipe.

- Clean any spilt fuel from the engine.

Installation

1. CAUTIONS:

Install new fuel injector leak off pipe retaining clips.

Make sure that the mating faces are clean and free of foreign material.

To install, reverse the removal procedure.

Electronic Engine Controls - TDV6 2.7L Diesel - Knock Sensor (KS) LH

Removal and Installation

Removal

- NOTE: Removal steps in this procedure may contain installation details.

1. Remove the crankcase vent oil separator.
For additional information, refer to: [Crankcase Vent Oil Separator \(303-08A Engine Emission Control - TDV6 2.7L Diesel, Removal and Installation\)](#).

2.  **WARNING:** Be prepared to collect escaping oil.

- NOTE: Remove and discard the O-ring seal.

Remove the engine oil filter.

- Loosen the element cover 4 complete turns to allow engine oil to drain from the filter cover.
- Remove element cover.

E52590

3. Disconnect the knock sensors (KS) electrical connector.

E100824

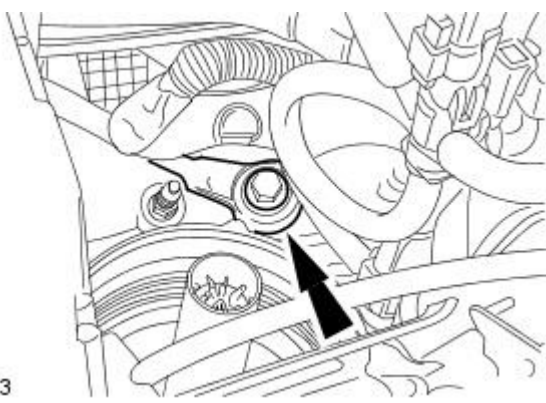

4. Disconnect the LH glow plug wiring harness electrical connector.

E63603

5.  CAUTION: Note the fitted position of the component prior to removal.

Remove the LH knock sensor (KS).

E52443

Installation

1. CAUTIONS:

 Make sure that the mating faces are clean and free of foreign material.

Electronic Engine Controls - V6 3.0L Petrol - Electronic Engine Controls - Overview

Description and Operation

OVERVIEW

The V6 3 Liter engine is controlled by an [ECM \(engine control module\)](#) manufactured by DENSO. The Engine Management System (EMS) controls the following:

- Engine fueling
- Ignition timing
- Closed loop fueling
- Knock control
- Idle speed control
- Emission control
- On Board Diagnostic
- Interface with the immobilization system
- Speed control

The [ECM](#) controls the engine fueling by providing sequential fuel injection to all cylinders. Ignition is controlled by a direct ignition system, provided by six plug top coils. The [ECM](#) is able to detect and correct for ignition knock on each cylinder and adjust the ignition timing for each cylinder to achieve optimum performance.

The [ECM](#) uses a torque-based strategy to generate the torque required by the driver and other vehicle control modules. The EMS uses various sensors to determine the torque required from the engine. The EMS also interfaces with other vehicle electronic control modules's, via the [CAN \(controller area network\)](#) bus, to obtain additional information (e.g. road speed from the [ABS \(anti-lock brake system\)](#) control module). The EMS processes these signals and decides how much torque to generate. Torque is then generated by using various actuators to supply air, fuel and spark to the engine (electronic throttle, injectors, coils, etc.).

The EMS comprises the following inputs:

- [CMP \(camshaft position\)](#) sensor
- [CKP \(crankshaft position\)](#) sensor
- Fuel rail pressure sensor
- MAF sensor
- Knock sensors
- Fuel rail temperature sensor
- [ECT \(engine coolant temperature\)](#) sensor
- Engine oil temperature sensor
- [MAP \(manifold absolute pressure\)](#) sensor
- Electric throttle feedback sensor
- [AIR \(secondary air injection\)MAP](#) sensor
- [APP \(accelerator pedal position\)](#) sensor
- Tank leakage detection system (NAS only)
- Cooling fan speed feedback
- Oxygen sensors
- Brake switch
- Speed control cancel/suspend switch
- Automatic speed limiter switch
- Crank request signal
- [IAT \(intake air temperature\)](#) sensor
- External air temperature sensor

The EMS comprises the following outputs:

- Fuel injectors
- Ignition coils
- Engine cooling fan
- Electric throttle
- Electric fuel pump driver module
- [VCT \(variable camshaft timing\)](#) solenoids
- Purge valve
- [EGR \(exhaust gas recirculation\)](#) valve
- [AIR](#) pump
- Starter relay control

System Operation

The [ECM](#) controls the engine fueling by providing sequential fuel injection to all cylinders. Ignition is controlled by a direct ignition system, provided by six plug top coils. The [ECM](#) is able to detect and correct for ignition knock on each cylinder and adjust the ignition timing for each cylinder to achieve optimum performance.

The [ECM](#) uses a torque-based strategy to generate the torque required by the driver and other vehicle control modules. The [ECM](#) uses various sensors to determine the torque required from the engine. The EMS also interfaces with other vehicle electronic control modules's, via the [CAN](#) bus, to obtain additional information (e.g. road speed from the [ABS](#) control module). The EMS processes these signals and decides how much torque to generate. Torque is then generated by using various actuators to supply air, fuel and spark to the engine (electronic throttle, injectors, coils, etc.).

System Inputs

The EMS has the following inputs:

- [RCM](#)
- Park/neutral switch
- Ignition coil feedback
- Fuel rail temperature
- [MAF](#)
- Engine speed
- Camshaft position
- Driver demand
- Brake pedal position switch
- Speed control switches
- Generator load
- [HO2S \(heated oxygen sensor\)](#) pre catalyst
- [HO2S](#) post catalyst
- Throttle position
- Cooling fan speed
- Ignition switch
- Knock sensors
- [MAP](#)
- [ECT \(engine coolant temperature\)](#)
- Engine oil temperature
- [EOP](#)
- Fuel pressure
- Fuel temperature

System Outputs

The EMS has the following outputs:

- Throttle Actuator
- Brake vacuum pump relay
- Ignition coils
- Oxygen sensor heaters
- Fuel injectors
- Purge Valve
- Engine Cooling Fan
- Fuel pump relay
- Starter Relay
- [ECM](#) Main Relay
- Generator Control
- Fuel tank leakage detection

ECM Adaptions

The [ECM](#) has the ability to adapt the values it uses to control certain outputs. This capability ensures the EMS can meet emissions legislation and improve the refinement of the engine throughout its operating range.

The components which have adaptions associated with them are:

- The [APP](#) sensor
- The oxygen sensors
- The [MAF/IAT \(intake air temperature\)](#) sensor
- The [CKP](#) sensor
- The Electric throttle body.

Oxygen Sensors and MAF/AT Sensor

There are several adaptive maps associated with the fueling strategy. Within the fueling strategy the [ECM](#) calculates short-term adaptions and long term adaptions. The [ECM](#) will monitor the deterioration of the oxygen sensors over a period of time. It will also monitor the current correction associated with the sensors.

The [ECM](#) will store a fault code in circumstances where an adaption is forced to exceed its operating parameters. At the same time, the [ECM](#) will record the engine speed, engine load and intake air temperature.

Crankshaft Position Sensor

The characteristics of the signal supplied by the [CKP](#) sensor is learnt by the [ECM](#). This enables the [ECM](#) to set an adaption and support the engine misfire detection function. Due to the small variation between different flywheels and different [CKP](#) sensors, the adaption must be reset if either component is renewed, or removed and refitted. It is also necessary to reset the flywheel adaption if the [ECM](#) is renewed or replaced. The [ECM](#) supports four flywheel adaptions for the [CKP](#) sensor. Each adaption relates to a specific engine speed range. The engine speed ranges are detailed in the table below:

Adaptions	Engine Speed, rev/min
1	1800 - 3000
2	3001 - 3800
3	3801 - 4600
4	4601 - 5400

Misfire Detection

Legislation requires that the [ECM](#) must be able to detect the presence of an engine misfire. It must be able to detect misfires at two separate levels. The first level is a misfire that could lead to the vehicle emissions exceeding 1.5 times the Federal Test Procedure (FTP) requirements for the engine. The second level is a misfire that may cause catalyst damage.

The [ECM](#) sensor monitors the number of misfire occurrences within two engine speed ranges. If the [ECM](#) detects more than a predetermined number of misfire occurrences within either of these two ranges, over two consecutive journeys, the [ECM](#) will record a fault code and details of the engine speed, engine load and engine coolant temperature. In addition, the [ECM](#) monitors the number of misfire occurrences that happen in a 'window' of 200 engine revolutions. The misfire occurrences are assigned a weighting according to their likely impact on the

catalysts. If the number of misfires exceeds a certain value, the [ECM](#) stores catalyst-damaging fault codes, along with the engine speed, engine load and engine coolant temperature.

The signal from the [CKP](#) indicates how fast the poles on the flywheel are passing the sensor tip. A sine wave is generated each time a pole passes the sensor tip. The [ECM](#) can detect variations in flywheel speed by monitoring the sine wave signal supplied by the [CKP](#) sensor.

By assessing this signal, the [ECM](#) can detect the presence of an engine misfire. At this time, the [ECM](#) will assess the amount of variation in the signal received from the [CKP](#) and assigns a roughness value to it. This roughness value can be viewed within the real time monitoring feature, using a Land Rover approved diagnostic system. The [ECM](#) will evaluate the signal against a number of factors and will decide whether to count the occurrence or ignore it. The [ECM](#) can assign a roughness and misfire signal for each cylinder, (i.e. identify which cylinder is misfiring).

Diagnostics

The [ECM](#) stores faults as [DTC \(diagnostic trouble code\)](#), referred to as 'P' codes. The 'P' codes are defined by [OBD \(on-board diagnostic\)](#) legislation and, together with their associated environmental and freeze frame data, can be read using a third party scan tool or a Land Rover approved diagnostic system. A Land Rover approved diagnostic system can also read real time data from each sensor, the adaptive values currently being employed and the current fueling, ignition and idle settings.

Component Description

Engine Control Module

The [ECM](#) is located in the engine bay attached to the bulkhead. On [LHD \(left-hand drive\)](#) vehicles the [ECM](#) is located on the [RH \(right-hand\)](#) side of the compartment behind the [BJB](#). On [RHD \(right-hand drive\)](#) vehicles the [ECM](#) is located on the [LH \(left-hand\)](#) side of the engine compartment.

The [ECM](#) controls the engine fueling by providing sequential fuel injection to all cylinders. Ignition is controlled by a direct ignition system, provided by eight plug top coils. The [ECM](#) is able to detect and correct for ignition knock on each cylinder and adjust the ignition timing for each cylinder to achieve optimum performance.

The [ECM](#) uses a torque-based strategy to generate the torque required by the driver and other vehicle control modules. The EMS uses various sensors to determine the torque required from the engine. The EMS also interfaces with other vehicle electronic control modules's, via the [CAN](#) bus, to obtain additional information (e.g. road speed from the [ABS](#) control module). The EMS processes these signals and decides how much torque to generate. Torque is then generated by using various actuators to supply air, fuel and spark to the engine (electronic throttle, injectors, coils, etc.).

Crankshaft Position Sensor (CKP)

E46331

The crankshaft position sensor is mounted at the rear underside of the engine near the transmission bell housing. Connection between the sensor and the harness is via a link harness and a two-way connector. Both wires go directly to the [ECM](#). The sensor produces the signal which enables the [ECM](#) to determine the angle of the crankshaft, and the engine rpm. From this, the point of ignition, fuel injection, etc. is calculated. If the signal wires are reversed a 3° advance in timing will occur, as the electronics within the [ECM](#) uses the falling edge of the signal waveform as its reference/timing point for each tooth.

The reluctor is pressed into the flywheel and has a "tooth" pattern based on 36 teeth at 10° intervals and approximately 5° wide: one of the teeth is removed to provide a hardware reference mark which is 60 degrees [BTDC \(before top dead center\)](#) No.1 cylinder. Because of the crankshaft sensor's orientation, the target wheel uses windows machined into the face, rather than actual teeth.

The sensor operates by generating an output voltage caused by the change in magnetic field that occurs as the windows pass in front of the sensor. The output voltage varies with the speed of the windows passing the sensor, the higher the engine speed, the higher the output voltage. Note that the output is also dependent on the air gap between the sensor and the teeth (the larger the gap, the weaker the signal, the lower the output voltage). The [ECM](#) transmits the engine speed to other vehicle control modules on [CAN](#).

Camshaft Position Sensor (CMP)

E46332

Two sensors are located at the rear of the engine, in the cylinder head (one per bank), above the rear cylinders. This is a Variable Reluctor Sensor (VRS) producing four pulses for every two engine revolutions. The sensing element is positioned between 0 and 2mm from the side of the cam gear wheel.

The variable cam intake is parked in the retarded position and can advance up to 48 degrees.

The camshaft timing wheel is a sintered component which has four teeth on it to enable the EMS to detect cylinder identification. The signal is used for:

- Variable intake cam timing
- Cylinder recognition
- Enabling sequential fuel injection
- Knock control
- Cylinder identification for diagnostic purposes.

Failure symptoms include:

- Ignition timing reverting to the base mapping, with no cylinder correction.
- Active knock control is disabled, along with its diagnostic (safe ignition map-loss of performance).
- Quick cam/crank synchronisation on start disabled.
- Variable cam timing is disabled

Engine coolant Temperature Sensor

E47309

The sensor is located at the front of the engine in the water pipe below the throttle body. The [ECT](#) sensor is a thermistor used to monitor the engine coolant temperature. The [ECT](#) sensor is vital to the correct running of the engine as a richer mixture is required at lower block temperatures for good quality starts and smooth running, leaning off as the temperature rises to maintain emissions and performance.

The sensor has an operating temperature range of -40 Degrees Celsius to 119 Degrees Celsius. When a defective coolant sensor is detected, the [ECM](#) uses the oil temperature sensor value. [PTC \(positive temperature coefficient\)](#)

Tank Leakage Detection-NAS ONLY

The tank leakage detection system periodically checks the evaporative system and the fuel tank for leaks when the ignition is switched off. The tank leakage detection pump is connected to the atmospheric vent of the charcoal cannister and incorporates a [PTC](#) heating element a normally open valve and a reference orifice. The tank leakage detection pump is only operated when the ignition is switched off and is controlled by the [ECM](#). The [ECM](#) also monitors the electric air pump operation and the normally open valve for faults. To check the fuel tank and EVAP system for leaks the [ECM](#) operates the tank leakage detection pump and monitors the current draw. This is compared to a referenced figure established from the current draw when air is pumped through the reference orifice.

Purge Valve

The purge valve is located at the rear of the engine on a bracket which is attached to the transmission bell housing. The purge valve is a solenoid operated valve which is closed when de-energized. The purge valve is controlled by a 10Hz [PWM \(pulse width modulation\)](#) signal from the [ECM](#). When the engine operating conditions are correct, the [ECM](#) opens the purge valve which causes fuel vapor and fresh air to be drawn through the charcoal cannister. The fresh air is drawn through the charcoal cannister via the tank leakage detection pump fresh air vent. [NTC \(negative temperature coefficient\)](#)

Engine Oil Temperature Sensor

E46333

Oil temperature is monitored through a temperature sensor mounted in the oil system. This component is a [NTC](#). The sensor is mounted next to the oil pressure sensor at the front of the engine and locates into the oil filter bracket.

Fuel Rail Temperature Sensor

E47606

The fuel rail temperature sensor measures the temperature of the fuel in the fuel rail. This input is then used to deliver the correct quantity of fuel to the engine. Operating Range -40 Degrees Celsius to 150 Degrees Celsius. The fuel rail temperature sensor is fitted on the rear of the right hand bank (bank A) fuel rail.

Mass Air Flow/Intake Air Temperature Sensor (MAF/IAT)

E47308

The air flow meter is located in the clean air duct immediately after the air filter box.

The air mass flow is determined by the cooling effect of intake air passing over a "hot film" element contained within the device. The higher the air flow the greater the cooling effect and the lower the electrical resistance of the "hot film" element. The [ECM](#) then uses this signal from the Mass Air Flow meter to calculate the air mass flowing into the engine.

The measured air mass flow is used in determining the fuel quantity to be injected in order to maintain the stoichiometric air/fuel mixture required for correct operation of the engine and exhaust catalysts. Should the device fail there is a software backup strategy that will be evoked once a fault has been diagnosed.

The following symptoms may be observed if the sensor fails:

- During driving the engine RPM might dip, before recovering.
- Difficulty in starting or start-stall.
- Poor throttle response/engine performance.
- Lambda control and idle speed control halted.
- Emissions incorrect.
- AFM signal offset

The [IAT](#) sensor is integrated into the [MAF](#) sensor. It is a temperature dependent resistor (thermistor), i.e. the resistance of the sensor varies with temperature. This thermistor is a [NTC](#) type element meaning that the sensor resistance decreases as the sensor temperature increases. The sensor forms part of a voltage divider chain with an additional resistor in the [ECM](#). The voltage from this sensor changes as the sensor resistance changes, thus relating the air temperature to the voltage measured by the [ECM](#).

The [ECM](#) stores a 25 Degrees Celsius default value for air temperature in the event of a sensor failure.

Manifold Absolute Pressure Sensor (MAP)

E47588

The [MAP](#) sensor provides a voltage proportional to the absolute pressure in the intake manifold. This signal allows the load on the engine to be calculated and used within the internal calculations of the [ECM](#). The sensor is located on the rear of the air intake manifold.

The output signal from the [MAP](#) sensor, together with the [CKP](#) and [IAT](#) sensors, is used by the [ECM](#) to calculate the amount of air induced

into the cylinders. This enables the [ECM](#) to determine ignition timing and fuel injection duration values.

The [MAP](#) sensor receives a 5V supply voltage from the [ECM](#) and provides an analogue signal to [ECM](#), which relates to the absolute manifold pressure and allows the [ECM](#) to calculate engine load. The [ECM](#) provides a ground for the sensor.

If the [MAP](#) signal is missing, the [ECM](#) will substitute a default manifold pressure reading based on crankshaft speed and throttle angle. The engine will continue to run with reduced drivability and increased emissions, although this may not be immediately apparent to the driver. The [ECM](#) will store fault codes which can be retrieved using the recommended Jaguar diagnostic tool.

Knock Sensors

The EMS has two knock sensors located in the V of the engine, one per cylinder bank. The sensors are connected to the [ECM](#) via a twisted pair of wires.

The knock sensors produce a voltage signal in proportion to the amount of mechanical vibration generated at each ignition point. Each sensor monitors the related cylinder bank.

The knock sensors incorporate a piezo-ceramic crystal. This crystal produces a voltage whenever an outside force tries to deflect it, (i.e. exerts a mechanical load on it). When the engine is running, the compression waves in the material of the cylinder block, caused by the combustion of the fuel/air mixture within the cylinders, deflect the crystal and produce an output voltage signal. The signals are supplied to the [ECM](#), which compares them with 'mapped' signals stored in memory. From this, the [ECM](#) can determine when detonation occurs on individual cylinders. When detonation is detected, the [ECM](#) retards the ignition timing on that cylinder for a number of engine cycles, then gradually returns it to the original setting.

Care must be taken at all times to avoid damaging the knock sensors, but particularly during removal and fitting procedures. The recommendations regarding torque and surface preparation must be adhered to. The torque applied to the sensor and the quality of the surface preparation both have an influence over the transfer of mechanical noise from the cylinder block to the crystal.

The [ECM](#) uses the signals supplied by the knock sensors, in conjunction with the signal it receives from the camshaft sensor, to determine the optimum ignition point for each cylinder. The ignition point is set according to preprogrammed ignition maps stored within the [ECM](#). The [ECM](#) is programmed to use ignition maps for 98 RON premium specification fuel. It will also function on 91 RON regular specification fuel and learn new adaptations. If the only fuel available is of poor quality, or the customer switches to a lower grade of fuel after using a high grade for a period of time, the engine may suffer slight pre-ignition for a short period. This amount of pre-ignition will not damage the engine. This situation will be evident while the [ECM](#) learns and then modifies its internal mapping to compensate for the variation in fuel quality. This feature is called adaption. The [ECM](#) has the capability of adapting its fuel and ignition control outputs in response to several sensor inputs.

The [ECM](#) will cancel closed loop control of the ignition system if the signal received from either knock sensor becomes implausible. In these circumstances the [ECM](#) will default to a safe ignition map. This measure ensures the engine will not become damaged if low quality fuel is used. The [MIL](#) (malfunction indicator lamp) will not illuminate, although the driver may notice that the engine 'pinks' in some driving conditions and displays a drop in performance and smoothness.

When a knock sensor fault is stored, the [ECM](#) will also store details of the engine speed, engine load and the coolant temperature.

Electric Throttle

The V6 EMS incorporates an electric throttle control system. The electronic throttle body is located on the air intake manifold in the engine compartment. The system comprises three main components:

- Electronic throttle control valve
- [APP](#)
- [ECM](#)

When the accelerator pedal is depressed the [APP](#) sensor provides a change in the monitored signals. The [ECM](#) compares this against an electronic "map" and moves the electronic throttle valve via a [PWM](#) control signal which is in proportion to the [APP](#) angle signal. The system is required to:

- Regulate the calculated intake air load based on the accelerator pedal sensor input signals and programmed mapping.
- Monitor the drivers input request for cruise control operation.
- Automatically position the electronic throttle for accurate cruise control.
- Perform all dynamic stability control throttle control interventions.
- Monitor and carry out maximum engine and road speed cut out.

A software strategy within the [ECM](#) enables the throttle position to be calibrated each ignition cycle. When the ignition is turned OFF, the [ECM](#) performs a self test and calibration routine on the electronic throttle by closing the throttle fully. The power is then removed and the [ECM](#) checks that the throttle returns to the reference position under the pressure from the spring.

Accelerator Pedal Position Sensor (APP)

The [APP](#) sensor is located in a plastic housing which is integral with the throttle pedal. The housing is injection molded and provides location for the [APP](#) sensor. The sensor is mounted externally on the housing and is secured with two Torx screws. The external body of the sensor has a six pin connector which accepts a connector on the vehicle wiring harness.

The sensor has a spigot which protrudes into the housing and provides the pivot point for the pedal mechanism. The spigot has a slot which allows for a pin, which is attached to the sensor potentiometers, to rotate through approximately 90 degrees, which relates to pedal movement. The pedal is connected via a link to a drum, which engages with the sensor pin, changing the linear movement of the pedal into rotary movement of the drum. The drum has two steel cables attached to it. The cables are secured to two tension springs which are secured in the opposite end of the housing. The springs provide 'feel' on the pedal movement and require an effort from the driver similar to that of a cable controlled throttle. A detente mechanism is located at the forward end of the housing and is operated by a ball located on the drum. At near maximum throttle pedal movement, the ball contacts the detente mechanism. A spring in the mechanism is compressed and gives the driver the feeling of depressing a 'kickdown' switch when full pedal travel is achieved.

The [APP](#) sensor signals are checked for range and plausibility. Two separate reference voltages are supplied to the pedal. Should one sensor fail, the other is used as a 'limp-home' input. In limp home mode due to an [APP](#) signal failure the [ECM](#) will limit the maximum engine speed to 2000 rpm.

APP Sensor Output Graph

M180795

ItemDescription

- A Voltage
- B APP sensor angle
- C Kick down angle

The APP sensor has two potentiometer tracks which each receive a 5V input voltage from the ECM. Track 1 provides an output of 0.5V with the pedal at rest and 2.0V at 100% full throttle. Track 2 provides an output of 0.5V with the pedal at rest and 4.5V at 100% full throttle. The signals from the two tracks are used by the ECM to determine fueling for engine operation and also by the ECM and the TCM to initiate a kickdown request for the automatic transmission.

The ECM monitors the outputs from each of the potentiometer tracks and can determine the position, rate of change and direction of movement of the throttle pedal. The 'closed throttle' position signal is used by the ECM to initiate idle speed control and also overrun fuel cut-off.

Oxygen Sensors

There are four oxygen sensors located in the exhaust system. Two upstream before the catalytic converter (HO2S) and two down stream after the catalytic converter (O2S). The sensor monitors the level of oxygen in the exhaust gases and is used to control the fuel/air mixture. Positioning a sensor in the stream of exhaust gasses from each bank enables the ECM to control the fueling on each bank independently of the other, allowing much closer control of the air/fuel ratio and catalyst conversion efficiency.

The oxygen sensors need to operate at high temperatures in order to function correctly. To achieve the high temperatures required, the sensors are fitted with heater elements that are controlled by a [PWM](#) signal from the [ECM](#). The heater elements are operated immediately following engine start and also during low load conditions when the temperature of the exhaust gases is insufficient to maintain the required sensor temperatures. A non-functioning heater delays the sensor's readiness for closed loop control and influences emissions. The [PWM](#) duty cycle is carefully controlled to prevent thermal shock to cold sensors.

[HO2S](#) sensors also known as Linear or "Wide Band" sensors produces a constant voltage, with a variable current that is proportional to the oxygen content. This allows closed loop fueling control to a target lambda, i.e. during engine warm up (after the sensor has reached operating temperature and is ready for operation). This improves emission control.

The [O2S](#) sensor uses Zirconium technology that produces an output voltage dependant upon the ratio of exhaust gas oxygen to the ambient oxygen. The device contains a Galvanic cell surrounded by a gas permeable ceramic, the voltage of which depends upon the level of [O2](#) (oxygen) diffusing through. Nominal output voltage of the device for $\lambda = 1$ is 300 to 500m volts. As the fuel mixture becomes richer ($\lambda < 1$) the voltage tends towards 900m volts and as it becomes leaner ($\lambda > 1$) the voltage tends towards 0 volts. Maximum tip temperature is 1,000 Degrees Celsius for a maximum of 100 hours.

Sensors age with mileage, increasing their response time to switch from rich to lean and lean to rich. This increase in response time influences the [ECM](#) closed loop control and leads to progressively increased emissions. Measuring the period of rich to lean and lean to rich switching monitors the response rate of the upstream sensors.

Diagnosis of electrical faults is continually monitored in both the upstream and downstream sensors. This is achieved by checking the signal against maximum and minimum threshold, for open and short circuit conditions.

Oxygen sensors must be treated with the utmost care before and during the fitting process. The sensors have ceramic material within them that can easily crack if dropped/banged or over-torqued. The sensors must be torqued to the required figure, (40-50Nm), with a calibrated torque wrench. Care should be taken not to contaminate the sensor tip when anti-seize compound is used on the thread. Heated sensor signal pins are tinned and universal are gold plated. Mixing up sensors could contaminate the connectors and affect system performance.

Failure Modes

- Mechanical fitting & integrity of the sensor.
- Sensor open circuit/disconnected.
- Short circuit to vehicle supply or ground.
- Lambda ratio outside operating band.
- Crossed sensors bank A & B.
- Contamination from leaded fuel or other sources.
- Change in sensor characteristic.
- Harness damage.
- Air leak into exhaust system.

Failure Symptoms

- Default to Open Loop fueling for the particular cylinder bank
- High [CO](#) (carbon monoxide) reading.
- Strong smell of [HO2S](#) till default condition.
- Excess Emissions.

It is possible to fit front and rear sensors in their opposite location. However the harness connections are of different gender and color to ensure that the sensors cannot be incorrectly connected. In addition to this the upstream sensors have two holes in the shroud, whereas the down stream sensors have four holes in the shroud for the gas to pass through.

Generator

E93662

The Generator has a power control module voltage regulator for use in a 14V charging system with 6÷12 zener diode bridge rectifiers.

The [ECM](#) monitors the load on the electrical system via [PWM](#) signal and adjusts the generator output to match the required load. The [ECM](#)

also monitors the battery temperature to determine the generator regulator set point. This characteristic is necessary to protect the battery; at low temperatures battery charge acceptance is very poor so the voltage needs to be high to maximize any rechargeability, but at high temperatures the charge voltage must be restricted to prevent excessive gassing of the battery with consequent water loss.

The Generator has a smart charge capability that will reduce the electrical load on the Generator reducing torque requirements, this is implemented to utilize the engine torque for other purposes. This is achieved by monitoring three signals to the [ECM](#):

- Generator sense (A sense), measures the battery voltage at the [CJB \(central junction box\)](#).
- Generator communication (Alt Com) communicates desired Generator voltage set point from [ECM](#) to Generator.
- Generator monitor (Alt Mon) communicates the extent of Generator current draw to [ECM](#). This signal also transmits faults to the [ECM](#) which will then send a message to the instrument pack on the [CAN](#) bus to illuminate the charge warning lamp.

Fuel Injectors

E47305

The engine has 6 fuel injectors (one per cylinder), each injector is directly driven by the [ECM](#). The injectors are fed by a common fuel rail as part of a 'returnless' fuel system. The fuel rail pressure is regulated to 4.5 bar by a fuel pressure regulator which is integral to the fuel pump module, within the fuel tank. The injectors can be checked by resistance checks. There is a fuel pressure test Schrader valve attached to the fuel rail on the front LH side for fuel pressure testing purposes. The [ECM](#) monitors the output power stages of the injector drivers for electrical faults.

The injectors have a resistance of 13.8 Ohms \pm 0.7 Ohms @ 20 Degrees Celsius.

Ignition Coils

E47306

The engine is fitted with six plug-top coils that are driven directly by the [ECM](#). This means that the [ECM](#), at the point where sufficient charge has built up, switches the primary circuit of each coil and a spark is produced in the spark plug. The positive supply to the coil is fed from a common fuse. Each coil contains a power stage to trigger the primary current. The [ECM](#) sends a signal to each of the coils power stage to trigger the power stage switching. Each bank has a feedback signal that is connected to each power stage. If the coil power stage has a failure the feedback signal is not sent, causing the [ECM](#) to store a fault code appropriate to the failure.

The [ECM](#) calculates the dwell time depending on battery voltage and engine speed to ensure constant secondary energy. This ensures sufficient secondary (spark) energy is always available, without excessive primary current flow thus avoiding overheating or damage to the coils.

The individual cylinder spark timing is calculated from a variety of inputs:

- Engine speed and load
- Engine temperature
- Knock control
- Auto gearbox shift control
- Idle speed control.

Fuel Rail Pressure Sensor

E58945

The fuel rail pressure sensor is located on top of the fuel rail adjacent to the fuel inlet. The fuel rail pressure sensor measures the pressure of the fuel in the fuel rail. This input is then used by the fuel pump control module to control the amount of fuel delivered to the fuel rail.

Fuel Pump Driver Module

E84483

The [FPDM](#) is located on the RH side of the charcoal canister on top of the fuel tank. The fuel pump control module receives a power supply via the fuel pump relay in the auxiliary fuse box.

The [ECM](#) sends a [PWM](#) signal to the [FPDM](#), the duty cycle of the signal determines the duty cycle of the pump. The [ECM](#) sets a target fuel pressure based on engine load. The target fuel pressure is maintained by using feedback from the fuel rail pressure sensor which is used to control the fuel pump via a closed loop [PWM](#) signal. The [PWM](#) signal to the pump represents half the ON time of the pump. If the [ECM](#) transmits a 50% on time the fuel pump control module drives the pump at 100%. If the [ECM](#) transmits a 5% ON time the fuel pump control module drives the pump at 10%. The fuel pump control module will only turn the fuel pump ON if it receives a valid signal between 4% and 50%. When the [ECM](#) requires the fuel pump to be turned OFF the [ECM](#) transmits a duty cycle signal of 75%.

The status of the [FPDM](#) is monitored by the [ECM](#). Any errors can be retrieved from the [ECM](#). The fuel pump control module cannot be interrogated for diagnostic purposes.

The [ECM](#) controls the [FPDM](#) in response to inputs from the fuel rail pressure sensor, [MAP](#) and the [MAF/IAT](#) sensor.

Variable Valve Timing (VVT)

Variable valve timing is used on the V6 engine to enhance low and high speed engine performance and idle speed quality.

For each intake camshaft the [VVT](#) (variable valve timing) system comprises:

- [VVT](#) unit
- Valve timing solenoid

The [VVT](#) system alters the phase of the intake valves relative to the fixed timing of the exhaust valves, to alter:

- The mass of air flow to the cylinders.
- The engine torque response.
- Emissions.

The [VVT](#) unit uses a vane type device to control the camshaft angle. The system operates over a range of 48 degrees and is advanced or retarded to its optimum position within this range.

The [VVT](#) system is controlled by the [ECM](#) based on engine load and speed along with engine oil temperature to calculate the appropriate camshaft position.

The [VVT](#) system provides the following advantages:

- Reduced engine emissions and improved fuel consumption which in turn improves the engines internal [EGR \(exhaust gas recirculation\)](#) effect over a wider operating range.
- Enhanced full load torque characteristics.
- Improved fuel economy through optimized torque over the engine speed range.

Variable Valve Timing Unit

E62237

ItemDescription

1	Vane housing
2	Vane shaft
3	Retard chamber
4	Rotation direction
5	Advance chamber oil channel
6	Stopper pin
7	Intake camshaft
8	Retard chamber oil channel
9	Advance chamber

The [VVT](#) unit is a hydraulic actuator mounted on the end of the intake camshaft. The unit advances or retards the camshaft timing to alter the camshaft to crankshaft phase. The [ECM](#) controls the [VVT](#) timing unit via an oil control solenoid. The oil control solenoid routes oil pressure to the advance or retard chambers either side of the vanes within the [VVT](#) unit.

The [VVT](#) unit is driven by the primary drive chain and rotates relative to the exhaust camshaft. When the [ECM](#) requests a retard in camshaft timing the oil control solenoid is energized which moves the shuttle valve in the solenoid to the relevant position allowing oil pressure to flow out of the advance chambers in the [VVT](#) unit whilst simultaneously allowing oil pressure into the retard chambers.

The [ECM](#) controls the advancing and retarding of the [VVT](#) unit based on engine load and speed. The [ECM](#) sends an energize signal to the oil control solenoid until the desired [VVT](#) position is achieved. When the desired [VVT](#) position is reached, the energizing signal is reduced to hold the oil control solenoid position and consequently desired [VVT](#) position. This function is under closed loop control and the [ECM](#) can sense any variance in shuttle valve oil pressure via the camshaft position sensor and can adjust the energizing signal to maintain the shuttle valve hold position.

operation can be affected by engine oil temperature and properties. At very low oil temperatures the movement of the [VVT](#) mechanism will be slow due to the high viscosity of the oil. While at high oil temperatures the low oil viscosity may impair the [VVT](#) operation at low oil pressures. The oil pump has the capacity to cope with these variations in oil pressure while an oil temperature sensor is monitored by the [ECM](#) to provide oil temperature feedback. At extremely high oil temperatures the [ECM](#) may limit the amount of [VVT](#) advance in order to prevent the engine from stalling when returning to idle speed.

[VVT](#) does not operate when engine oil pressure is below 1.25 bar. This is because there is insufficient pressure to release the [VVT](#) units internal stopper pin. This occurs when the engine is shut down and the [VVT](#) unit has returned to the retarded position. The stopper pin locks the [VVT](#) unit to the camshaft to ensure camshaft stability during the next start up.

Valve Timing Solenoid

E47302

Valve Timing Solenoid

The valve timing solenoid controls the position of the shuttle valve in the bush carrier. A plunger on the solenoid extends when the solenoid is energized and retracts when the solenoid is de-energized.

When the valve timing solenoids are de-energized, the coil springs in the bush carriers position the shuttle valves to connect the valve timing units to drain. In the valve timing units, the return springs hold the ring pistons and gears in the retarded position. When the valve timing solenoids are energized by the [ECM](#), the solenoid plungers position the shuttle valves to direct engine oil to the valve timing units. In the valve timing units, the oil pressure overcomes the force of the return springs and moves the gears and ring pistons to the advanced position. System response times are 1.0 second maximum for advancing and 0.7 second maximum for retarding. While the valve timing is in the retarded mode, the [ECM](#) produces a periodic lubrication pulse. This momentarily energizes the valve timing solenoids to allow a spurt of oil into the valve timing units. The lubrication pulse occurs once every 5 minutes.

Electronic Engine Controls - V6 3.0L Petrol - Electronic Engine Controls

Diagnosis and Testing

Principles of Operation

For a detailed description of the 3.0L petrol electronic engine controls, refer to the relevant Description and Operation section in the workshop manual. REFER to: (303-14B Electronic Engine Controls - V6 3.0L Petrol)

Electronic Engine Controls - V6 3.0L Petrol - Camshaft Position (CMP) Sensor LH

Removal and Installation

Removal

- NOTE: Some variation in the illustrations may occur, but the essential information is always correct.
- NOTE: Removal steps in this procedure may contain installation details.

1. Disconnect the battery ground cable.
For additional information, refer to: Battery Disconnect and Connect (414-01, General Procedures).
2. Remove the air cleaner outlet pipe.
For additional information, refer to: [Air Cleaner Outlet Pipe](#) (303-12B Intake Air Distribution and Filtering - V6 3.0L Petrol, Removal and Installation).
3. TORQUE: 12 Nm

4.  CAUTION: A new O-ring seal is to be installed.

TORQUE: 7 Nm

Installation

1. To install, reverse the removal procedure.

Electronic Engine Controls - V6 3.0L Petrol - Camshaft Position (CMP) Sensor RH

Removal and Installation

Removal

- NOTE: Removal steps in this procedure may contain installation details.
- NOTE: Some illustrations may show the engine removed for clarity.

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01, General Procedures).
2. Remove the throttle body.
For additional information, refer to: [Throttle Body](#) (303-04C Fuel Charging and Controls - V6 3.0L Petrol, Removal and Installation).
3. TORQUE: 7 Nm

Installation

1. To install, reverse the removal procedure.

Electronic Engine Controls - V6 3.0L Petrol - Catalyst Monitor Sensor

Removal and Installation

General Equipment

Snap-on tool S6176

Removal

1. Raise and support the vehicle.
For additional information, refer to Section [100-02 Jacking and Lifting](#).
2. Disconnect the catalyst monitor sensor.

3.  CAUTION: Make sure the wiring harness is not twisted or damaged on removal. Failure to follow this instruction may result in damage to the vehicle.

Using the Snap-on tool S6176, remove the catalyst monitor sensor.

Installation

1.  CAUTION: Make sure the wiring harness is not twisted or damaged on installation. Failure to follow this instruction may result in damage to the vehicle.

To install, reverse the removal procedure.

- Tighten to 45 Nm.

Electronic Engine Controls - V6 3.0L Petrol - Crankshaft Position (CKP) Sensor

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2.  **WARNING:** Make sure to support the vehicle with axle stands.

Raise and support the vehicle.
3. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
4. Disconnect the crankshaft position (CKP) sensor electrical connector.

5. Remove the CKP sensor.

Installation

1. To install, reverse the removal procedure.
 - Tighten to 10 Nm.

Electronic Engine Controls - V6 3.0L Petrol - Engine Control Module (ECM)

Removal and Installation

Removal

All vehicles

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the cowl vent screen.
For additional information, refer to: [Cowl Vent Screen](#) (501-02 Front End Body Panels, Removal and Installation).

Right-hand drive vehicles

3. Remove the secondary bulkhead LH panel.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Electronic Engine Controls - Overview

Description and Operation

Overview

The V8 4.2 Liter naturally aspirated and supercharged engines are controlled by an [ECM \(engine control module\)](#) manufactured by DENSO. The Engine Management System (EMS) controls the following:

- Engine fueling
- Ignition timing
- Closed loop fueling
- Knock control
- Idle speed control
- Emission control
- [OBD \(on-board diagnostic\)](#)
- Interface with the immobilization system
- Speed control

The [ECM](#) controls the engine fueling by providing sequential fuel injection to all cylinders. Ignition is controlled by a direct ignition system, provided by eight plug top coils. The [ECM](#) is able to detect and correct for ignition knock on each cylinder and adjust the ignition timing for each cylinder to achieve optimum performance.

The [ECM](#) uses a torque-based strategy to generate the torque required by the driver and other vehicle control modules. The EMS uses various sensors to determine the torque required from the engine. The EMS also interfaces with other vehicle electronic control modules's, via the [CAN \(controller area network\)](#) bus, to obtain additional information (e.g. road speed from the [ABS \(anti-lock brake system\)](#) control module). The EMS processes these signals and decides how much torque to generate. Torque is then generated by using various actuators to supply air, fuel and spark to the engine (electronic throttle, injectors, coils, etc.).

The EMS comprises the following inputs:

- [CMP \(camshaft position\)](#) sensor
- [CKP \(crankshaft position\)](#) sensor
- Fuel rail pressure sensor
- [MAF \(mass air flow\)](#) sensor
- Knock sensors
- Fuel rail temperature sensor
- [ECT \(engine coolant temperature\)](#) sensor
- Engine oil temperature sensor
- [MAP \(manifold absolute pressure\)](#) sensor
- Electric throttle feedback sensor
- [AIR \(secondary air injection\)/MAP](#) sensor
- [APP \(accelerator pedal position\)](#) sensor
- Fuel tank leakage monitoring (NAS only)
- Cooling fan speed feedback
- [HO2S \(heated oxygen sensor\)](#)
- Brake switch
- Speed control cancel/suspend switch
- Automatic speed limiter switch
- Crank request signal
- [IAT \(intake air temperature\)](#) sensor
- External air temperature sensor

The EMS comprises the following outputs:

- Fuel injectors
- Ignition coils
- Engine cooling fan
- Electric throttle
- Electric fuel pump driver module
- [VCT \(variable camshaft timing\)](#) solenoids
- Purge valve
- [EGR \(exhaust gas recirculation\)](#) valve
- [AIR](#) pump
- Starter relay control

System Operation

The [ECM](#) controls the engine fueling by providing sequential fuel injection to all cylinders. Ignition is controlled by a direct ignition system, provided by six plug top coils. The [ECM](#) is able to detect and correct for ignition knock on each cylinder and adjust the ignition timing for each cylinder to achieve optimum performance.

The [ECM](#) uses a torque-based strategy to generate the torque required by the driver and other vehicle control modules. The [ECM](#) uses various sensors to determine the torque required from the engine. The EMS also interfaces with other vehicle electronic control modules's, via the [CAN](#) bus, to obtain additional information (e.g. road speed from the [ABS](#) control module). The EMS processes these signals and decides how much torque to generate. Torque is then generated by using various actuators to supply air, fuel and spark to the engine (electronic throttle, injectors, coils, etc.).

System Inputs

The EMS has the following inputs:

- [RCM](#)
- Park/neutral switch
- Ignition coil feedback
- Fuel rail temperature
- [MAF](#)
- Engine speed
- Camshaft position
- Driver demand
- Brake pedal position switch
- Speed control switches
- Generator load
- [HO2S \(heated oxygen sensor\)](#) pre catalyst
- [HO2S](#) post catalyst
- Throttle position
- Cooling fan speed
- Ignition switch
- Knock sensors
- [MAP](#)
- [ECT \(engine coolant temperature\)](#)
- Engine oil temperature
- [EOP](#)
- Fuel pressure
- Fuel temperature

System Outputs

The EMS has the following outputs:

- Throttle Actuator
- Brake vacuum pump relay
- Ignition coils
- Oxygen sensor heaters
- Fuel injectors
- Purge Valve
- Engine Cooling Fan
- Fuel pump relay
- Starter Relay
- [ECM](#) Main Relay
- Generator Control
- Fuel tank leakage detection

ECM Adaptions

The [ECM](#) has the ability to adapt the values it uses to control certain outputs. This capability ensures the EMS can meet emissions legislation and improve the refinement of the engine throughout its operating range.

The components which have adaptions associated with them are:

- The [APP](#) sensor
- The oxygen sensors
- The [MAF/IAT \(intake air temperature\)](#) sensor
- The [CKP](#) sensor
- The Electric throttle body.

Oxygen Sensors and MAF/AT Sensor

There are several adaptive maps associated with the fueling strategy. Within the fueling strategy the [ECM](#) calculates short-term adaptions and long term adaptions. The [ECM](#) will monitor the deterioration of the oxygen sensors over a period of time. It will also monitor the current correction associated with the sensors.

The [ECM](#) will store a fault code in circumstances where an adaption is forced to exceed its operating parameters. At the same time, the [ECM](#) will record the engine speed, engine load and intake air temperature.

Crankshaft Position Sensor

The characteristics of the signal supplied by the [CKP](#) sensor is learnt by the [ECM](#). This enables the [ECM](#) to set an adaption and support the engine misfire detection function. Due to the small variation between different flywheels and different [CKP](#) sensors, the adaption must be reset if either component is renewed, or removed and refitted. It is also necessary to reset the flywheel adaption if the [ECM](#) is renewed or replaced. The [ECM](#) supports four flywheel adaptations for the [CKP](#) sensor. Each adaptation relates to a specific engine speed range. The engine speed ranges are detailed in the table below:

Adaptions	Engine Speed, rev/min
1	1800 - 3000
2	3001 - 3800
3	3801 - 4600
4	4601 - 5400

Misfire Detection

Legislation requires that the [ECM](#) must be able to detect the presence of an engine misfire. It must be able to detect misfires at two separate levels. The first level is a misfire that could lead to the vehicle emissions exceeding 1.5 times the Federal Test Procedure (FTP) requirements for the engine. The second level is a misfire that may cause catalyst damage.

The [ECM](#) sensor monitors the number of misfire occurrences within two engine speed ranges. If the [ECM](#) detects more than a predetermined number of misfire occurrences within either of these two ranges, over two consecutive journeys, the [ECM](#) will record a fault code and details of the engine speed, engine load and engine coolant temperature. In addition, the [ECM](#) monitors the number of misfire occurrences that happen in a 'window' of 200 engine revolutions. The misfire occurrences are assigned a weighting according to their likely impact on the catalysts. If the number of misfires exceeds a certain value, the [ECM](#) stores catalyst-damaging fault codes, along with the engine speed, engine load and engine coolant temperature.

The signal from the [CKP](#) indicates how fast the poles on the flywheel are passing the sensor tip. A sine wave is generated each time a pole passes the sensor tip. The [ECM](#) can detect variations in flywheel speed by monitoring the sine wave signal supplied by the [CKP](#) sensor.

By assessing this signal, the [ECM](#) can detect the presence of an engine misfire. At this time, the [ECM](#) will assess the amount of variation in the signal received from the [CKP](#) and assigns a roughness value to it. This roughness value can be viewed within the real time monitoring feature, using a Land Rover approved diagnostic system. The [ECM](#) will evaluate the signal against a number of factors and will decide whether to count the occurrence or ignore it. The [ECM](#) can assign a roughness and misfire signal for each cylinder, (i.e. identify which cylinder is misfiring).

Diagnostics

The [ECM](#) stores faults as [DTC \(diagnostic trouble code\)](#), referred to as 'P' codes. The 'P' codes are defined by [OBD \(on-board diagnostic\)](#) legislation and, together with their associated environmental and freeze frame data, can be read using a third party scan tool or a Land Rover approved diagnostic system. A Land Rover approved diagnostic system can also read real time data from each sensor, the adaptive values currently being employed and the current fueling, ignition and idle settings.

Component Description

Engine Control Module

The [ECM](#) is located in the engine bay attached to the bulkhead. On [LHD \(left-hand drive\)](#) vehicles the [ECM](#) is located on the [RH \(right-hand\)](#) side of the compartment behind the [BJB](#). On [RHD \(right-hand drive\)](#) vehicles the [ECM](#) is located on the [LH \(left-hand\)](#) side of the engine compartment.

The [ECM](#) controls the engine fueling by providing sequential fuel injection to all cylinders. Ignition is controlled by a direct ignition system, provided by eight plug top coils. The [ECM](#) is able to detect and correct for ignition knock on each cylinder and adjust the ignition timing for each cylinder to achieve optimum performance.

The [ECM](#) uses a torque-based strategy to generate the torque required by the driver and other vehicle control modules. The EMS uses various sensors to determine the torque required from the engine. The EMS also interfaces with other vehicle electronic control modules's, via the [CAN](#) bus, to obtain additional information (e.g. road speed from the [ABS](#) control module). The EMS processes these signals and decides how much torque to generate. Torque is then generated by using various actuators to supply air, fuel and spark to the engine (electronic throttle, injectors, coils, etc.).

Crankshaft Position Sensor (CKP)

The crankshaft position sensor is mounted at the rear underside of the engine near the transmission bell housing. Connection between the sensor and the harness is via a link harness and a two-way connector. Both wires go directly to the [ECM](#). The sensor produces the signal which enables the [ECM](#) to determine the angle of the crankshaft, and the engine rpm. From this, the point of ignition, fuel injection, etc. is calculated. If the signal wires are reversed a 3° advance in timing will occur, as the electronics within the [ECM](#) uses the falling edge of the signal waveform as its reference/timing point for each tooth.

The reluctor is pressed into the flywheel and has a "tooth" pattern based on 36 teeth at 10° intervals and approximately 5° wide: one of the teeth is removed to provide a hardware reference mark which is 60 degrees [BTDC \(before top dead center\)](#) No.1 cylinder. Because of the crankshaft sensor's orientation, the target wheel uses windows machined into the face, rather than actual teeth.

The sensor operates by generating an output voltage caused by the change in magnetic field that occurs as the windows pass in front of the sensor. The output voltage varies with the speed of the windows passing the sensor, the higher the engine speed, the higher the output voltage. Note that the output is also dependent on the air gap between the sensor and the teeth (the larger the gap, the weaker the signal, the lower the output voltage). The [ECM](#) transmits the engine speed to other vehicle control modules on [CAN](#).

Camshaft Position Sensor (CMP)

E46332

Two sensors are located at the rear of the engine, in the cylinder head (one per bank), above the rear cylinders. This is a Variable Reluctor Sensor (VRS) producing four pulses for every two engine revolutions. The sensing element is positioned between 0 and 2mm from the side of the cam gear wheel.

The variable cam intake is parked in the retarded position and can advance up to 48 degrees.

The camshaft timing wheel is a sintered component which has four teeth on it to enable the EMS to detect cylinder identification. The signal is used for:

- Variable intake cam timing
- Cylinder recognition
- Enabling sequential fuel injection
- Knock control
- Cylinder identification for diagnostic purposes.

Failure symptoms include:

- Ignition timing reverting to the base mapping, with no cylinder correction.
- Active knock control is disabled, along with its diagnostic (safe ignition map-loss of performance).
- Quick cam/crank synchronisation on start disabled.
- Variable cam timing is disabled

Engine coolant Temperature Sensor

E47309

The sensor is located at the front of the engine in the water pipe below the throttle body. The [ECT](#) sensor is a thermistor used to monitor the engine coolant temperature. The [ECT](#) sensor is vital to the correct running of the engine as a richer mixture is required at lower block temperatures for good quality starts and smooth running, leaning off as the temperature rises to maintain emissions and performance.

The sensor has an operating temperature range of -40 Degrees Celsius to 119 Degrees Celsius. When a defective coolant sensor is detected, the [ECM](#) uses the oil temperature sensor value. [PTC \(positive temperature coefficient\)](#)

Tank Leakage Detection-NAS ONLY

The tank leakage detection system periodically checks the evaporative system and the fuel tank for leaks when the ignition is switched off. The tank leakage detection pump is connected to the atmospheric vent of the charcoal cannister and incorporates a [PTC](#) heating element a normally open valve and a reference orifice. The tank leakage detection pump is only operated when the ignition is switched off and is controlled by the [ECM](#). The [ECM](#) also monitors the electric air pump operation and the normally open valve for faults. To check the fuel tank and EVAP system for leaks the [ECM](#) operates the tank leakage detection pump and monitors the current draw. This is compared to a referenced figure established from the current draw when air is pumped through the reference orifice.

Purge Valve

The purge valve is located at the rear of the engine on a bracket which is attached to the transmission bell housing. The purge valve is a solenoid operated valve which is closed when de-energized. The purge valve is controlled by a 10Hz [PWM \(pulse width modulation\)](#) signal from the [ECM](#). When the engine operating conditions are correct, the [ECM](#) opens the purge valve which causes fuel vapor and fresh air to be drawn through the charcoal cannister. The fresh air is drawn through the charcoal cannister via the tank leakage detection pump fresh air vent. [NTC \(negative temperature coefficient\)](#)

Engine Oil Temperature Sensor

E46333

Oil temperature is monitored through a temperature sensor mounted in the oil system. This component is a [NTC](#). The sensor is mounted next to the oil pressure sensor at the front of the engine and locates into the oil filter bracket.

Fuel Rail Temperature Sensor

E47606

The fuel rail temperature sensor measures the temperature of the fuel in the fuel rail. This input is then used to deliver the correct quantity of fuel to the engine. Operating Range -40 Degrees Celsius to 150 Degrees Celsius. The fuel rail temperature sensor is fitted on the rear of the right hand bank (bank A) fuel rail.

Mass Air Flow/Intake Air Temperature Sensor (MAF/IAT)

E47308

The air flow meter is located in the clean air duct immediately after the air filter box.

The air mass flow is determined by the cooling effect of intake air passing over a “hot film” element contained within the device. The higher the air flow the greater the cooling effect and the lower the electrical resistance of the “hot film” element. The [ECM](#) then uses this signal from the Mass Air Flow meter to calculate the air mass flowing into the engine.

The measured air mass flow is used in determining the fuel quantity to be injected in order to maintain the stoichiometric air/fuel mixture required for correct operation of the engine and exhaust catalysts. Should the device fail there is a software backup strategy that will be evoked once a fault has been diagnosed.

The following symptoms may be observed if the sensor fails:

- During driving the engine RPM might dip, before recovering.
- Difficulty in starting or start-stall.
- Poor throttle response/engine performance.
- Lambda control and idle speed control halted.
- Emissions incorrect.
- AFM signal offset

The [IAT](#) sensor is integrated into the [MAF](#) sensor. It is a temperature dependent resistor (thermistor), i.e. the resistance of the sensor varies with temperature. This thermistor is a [NTC](#) type element meaning that the sensor resistance decreases as the sensor temperature increases. The sensor forms part of a voltage divider chain with an additional resistor in the [ECM](#). The voltage from this sensor changes as the sensor resistance changes, thus relating the air temperature to the voltage measured by the [ECM](#).

The [ECM](#) stores a 25 Degrees Celsius default value for air temperature in the event of a sensor failure.

Manifold Absolute Pressure Sensor (MAP)

E47588

The [MAP](#) sensor provides a voltage proportional to the absolute pressure in the intake manifold. This signal allows the load on the engine to be calculated and used within the internal calculations of the [ECM](#). The sensor is located on the rear of the air intake manifold.

The output signal from the [MAP](#) sensor, together with the [CKP](#) and [IAT](#) sensors, is used by the [ECM](#) to calculate the amount of air induced into the cylinders. This enables the [ECM](#) to determine ignition timing and fuel injection duration values.

The [MAP](#) sensor receives a 5V supply voltage from the [ECM](#) and provides an analogue signal to [ECM](#), which relates to the absolute manifold pressure and allows the [ECM](#) to calculate engine load. The [ECM](#) provides a ground for the sensor.

If the [MAP](#) signal is missing, the [ECM](#) will substitute a default manifold pressure reading based on crankshaft speed and throttle angle. The engine will continue to run with reduced drivability and increased emissions, although this may not be immediately apparent to the driver. The [ECM](#) will store fault codes which can be retrieved using the recommended Jaguar diagnostic tool.

Knock Sensors

E47296

The EMS has two knock sensors located in the V of the engine, one per cylinder bank. The sensors are connected to the [ECM](#) via a twisted pair of wires.

The knock sensors produce a voltage signal in proportion to the amount of mechanical vibration generated at each ignition point. Each sensor monitors the related cylinder bank.

The knock sensors incorporate a piezo-ceramic crystal. This crystal produces a voltage whenever an outside force tries to deflect it, (i.e. exerts a mechanical load on it). When the engine is running, the compression waves in the material of the cylinder block, caused by the combustion of the fuel/air mixture within the cylinders, deflect the crystal and produce an output voltage signal. The signals are supplied to the [ECM](#), which compares them with 'mapped' signals stored in memory. From this, the [ECM](#) can determine when detonation occurs on individual cylinders. When detonation is detected, the [ECM](#) retards the ignition timing on that cylinder for a number of engine cycles, then gradually returns it to the original setting.

Care must be taken at all times to avoid damaging the knock sensors, but particularly during removal and fitting procedures. The recommendations regarding torque and surface preparation must be adhered to. The torque applied to the sensor and the quality of the surface preparation both have an influence over the transfer of mechanical noise from the cylinder block to the crystal.

The [ECM](#) uses the signals supplied by the knock sensors, in conjunction with the signal it receives from the camshaft sensor, to determine the optimum ignition point for each cylinder. The ignition point is set according to preprogrammed ignition maps stored within the [ECM](#). The [ECM](#) is programmed to use ignition maps for 98 RON premium specification fuel. It will also function on 91 RON regular specification fuel and learn new adaptations. If the only fuel available is of poor quality, or the customer switches to a lower grade of fuel after using a high grade for a period of time, the engine may suffer slight pre-ignition for a short period. This amount of pre-ignition will not damage the engine. This situation will be evident while the [ECM](#) learns and then modifies its internal mapping to compensate for the variation in fuel quality. This feature is called adaptation. The [ECM](#) has the capability of adapting its fuel and ignition control outputs in response to several sensor inputs.

The [ECM](#) will cancel closed loop control of the ignition system if the signal received from either knock sensor becomes implausible. In these circumstances the [ECM](#) will default to a safe ignition map. This measure ensures the engine will not become damaged if low quality fuel is used. The [MIL \(malfunction indicator lamp\)](#) lamp will not illuminate, although the driver may notice that the engine 'pinks' in some driving conditions and displays a drop in performance and smoothness.

When a knock sensor fault is stored, the [ECM](#) will also store details of the engine speed, engine load and the coolant temperature.

Electric Throttle

E47298

The V6 EMS incorporates an electric throttle control system. The electronic throttle body is located on the air intake manifold in the engine compartment. The system comprises three main components:

- Electronic throttle control valve
- [APP](#)
- [ECM](#)

When the accelerator pedal is depressed the [APP](#) sensor provides a change in the monitored signals. The [ECM](#) compares this against an electronic "map" and moves the electronic throttle valve via a [PWM](#) control signal which is in proportion to the [APP](#) angle signal. The system is required to:

- Regulate the calculated intake air load based on the accelerator pedal sensor input signals and programmed mapping.
- Monitor the drivers input request for cruise control operation.
- Automatically position the electronic throttle for accurate cruise control.
- Perform all dynamic stability control throttle control interventions.
- Monitor and carry out maximum engine and road speed cut out.

A software strategy within the [ECM](#) enables the throttle position to be calibrated each ignition cycle. When the ignition is turned OFF, the [ECM](#) performs a self test and calibration routine on the electronic throttle by closing the throttle fully. The power is then removed and the [ECM](#) checks that the throttle returns to the reference position under the pressure from the spring.

Accelerator Pedal Position Sensor (APP)

E75881

The [APP](#) sensor is located in a plastic housing which is integral with the throttle pedal. The housing is injection molded and provides location for the [APP](#) sensor. The sensor is mounted externally on the housing and is secured with two Torx screws. The external body of the sensor has a six pin connector which accepts a connector on the vehicle wiring harness.

The sensor has a spigot which protrudes into the housing and provides the pivot point for the pedal mechanism. The spigot has a slot which allows for a pin, which is attached to the sensor potentiometers, to rotate through approximately 90 degrees, which relates to pedal movement. The pedal is connected via a link to a drum, which engages with the sensor pin, changing the linear movement of the pedal into rotary movement of the drum. The drum has two steel cables attached to it. The cables are secured to two tension springs which are secured in the opposite end of the housing. The springs provide 'feel' on the pedal movement and require an effort from the driver similar to that of a cable controlled throttle. A detente mechanism is located at the forward end of the housing and is operated by a ball located on the drum. At near maximum throttle pedal movement, the ball contacts the detente mechanism. A spring in the mechanism is compressed and gives the driver the feeling of depressing a 'kickdown' switch when full pedal travel is achieved.

The [APP](#) sensor signals are checked for range and plausibility. Two separate reference voltages are supplied to the pedal. Should one sensor fail, the other is used as a 'limp-home' input. In limp home mode due to an [APP](#) signal failure the [ECM](#) will limit the maximum engine speed to 2000 rpm.

APP Sensor Output Graph

M180795

ItemDescription

A	Voltage
B	APP sensor angle
C	Kick down angle

The APP sensor has two potentiometer tracks which each receive a 5V input voltage from the ECM. Track 1 provides an output of 0.5V with the pedal at rest and 2.0V at 100% full throttle. Track 2 provides an output of 0.5V with the pedal at rest and 4.5V at 100% full throttle. The signals from the two tracks are used by the ECM to determine fueling for engine operation and also by the ECM and the TCM to initiate a kickdown request for the automatic transmission.

The ECM monitors the outputs from each of the potentiometer tracks and can determine the position, rate of change and direction of movement of the throttle pedal. The 'closed throttle' position signal is used by the ECM to initiate idle speed control and also overrun fuel cut-off.

Oxygen Sensors

There are four oxygen sensors located in the exhaust system. Two upstream before the catalytic converter ([HO2S](#)) and two down stream after the catalytic converter ([O2S](#)). The sensor monitors the level of oxygen in the exhaust gases and is used to control the fuel/air mixture. Positioning a sensor in the stream of exhaust gasses from each bank enables the [ECM](#) to control the fueling on each bank independently of the other, allowing much closer control of the air/fuel ratio and catalyst conversion efficiency.

The oxygen sensors need to operate at high temperatures in order to function correctly. To achieve the high temperatures required, the sensors are fitted with heater elements that are controlled by a [PWM](#) signal from the [ECM](#). The heater elements are operated immediately following engine start and also during low load conditions when the temperature of the exhaust gases is insufficient to maintain the required sensor temperatures. A non-functioning heater delays the sensor's readiness for closed loop control and influences emissions. The [PWM](#) duty cycle is carefully controlled to prevent thermal shock to cold sensors.

[HO2S](#) sensors also known as Linear or "Wide Band" sensors produces a constant voltage, with a variable current that is proportional to the oxygen content. This allows closed loop fueling control to a target lambda, i.e. during engine warm up (after the sensor has reached operating temperature and is ready for operation). This improves emission control.

The [O2S](#) sensor uses Zirconium technology that produces an output voltage dependant upon the ratio of exhaust gas oxygen to the ambient oxygen. The device contains a Galvanic cell surrounded by a gas permeable ceramic, the voltage of which depends upon the level of [O2 \(oxygen\)](#) defusing through. Nominal output voltage of the device for $\lambda = 1$ is 300 to 500m volts. As the fuel mixture becomes richer ($\lambda < 1$) the voltage tends towards 900m volts and as it becomes leaner ($\lambda > 1$) the voltage tends towards 0 volts. Maximum tip temperature is 1,000 Degrees Celsius for a maximum of 100 hours.

Sensors age with mileage, increasing their response time to switch from rich to lean and lean to rich. This increase in response time influences the [ECM](#) closed loop control and leads to progressively increased emissions. Measuring the period of rich to lean and lean to rich switching monitors the response rate of the upstream sensors.

Diagnosis of electrical faults is continually monitored in both the upstream and downstream sensors. This is achieved by checking the signal against maximum and minimum threshold, for open and short circuit conditions.

Oxygen sensors must be treated with the utmost care before and during the fitting process. The sensors have ceramic material within them that can easily crack if dropped/banged or over-torqued. The sensors must be torqued to the required figure, (40-50Nm), with a calibrated torque wrench. Care should be taken not to contaminate the sensor tip when anti-seize compound is used on the thread. Heated sensor signal pins are tinned and universal are gold plated. Mixing up sensors could contaminate the connectors and affect system performance.

Failure Modes

- Mechanical fitting & integrity of the sensor.
- Sensor open circuit/disconnected.
- Short circuit to vehicle supply or ground.
- Lambda ratio outside operating band.
- Crossed sensors bank A & B.
- Contamination from leaded fuel or other sources.
- Change in sensor characteristic.
- Harness damage.
- Air leak into exhaust system.

Failure Symptoms

- Default to Open Loop fueling for the particular cylinder bank
- High [CO \(carbon monoxide\)](#) reading.
- Strong smell of [HO2S](#) till default condition.
- Excess Emissions.

It is possible to fit front and rear sensors in their opposite location. However the harness connections are of different gender and color to ensure that the sensors cannot be incorrectly connected. In addition to this the upstream sensors have two holes in the shroud, whereas the down stream sensors have four holes in the shroud for the gas to pass through.

Generator

E93662

The Generator has a power control module voltage regulator for use in a 14V charging system with 6÷12 zener diode bridge rectifiers.

The [ECM](#) monitors the load on the electrical system via [PWM](#) signal and adjusts the generator output to match the required load. The [ECM](#) also monitors the battery temperature to determine the generator regulator set point. This characteristic is necessary to protect the battery; at low temperatures battery charge acceptance is very poor so the voltage needs to be high to maximize any rechargeability, but at high temperatures the charge voltage must be restricted to prevent excessive gassing of the battery with consequent water loss.

The Generator has a smart charge capability that will reduce the electrical load on the Generator reducing torque requirements, this is implemented to utilize the engine torque for other purposes. This is achieved by monitoring three signals to the [ECM](#):

- Generator sense (A sense), measures the battery voltage at the [CJB \(central junction box\)](#).
- Generator communication (Alt Com) communicates desired Generator voltage set point from [ECM](#) to Generator.
- Generator monitor (Alt Mon) communicates the extent of Generator current draw to [ECM](#). This signal also transmits faults to the [ECM](#) which will then sends a message to the instrument pack on the [CAN](#) bus to illuminate the charge warning lamp.

Fuel Injectors

E47305

The engine has 6 fuel injectors (one per cylinder), each injector is directly driven by the [ECM](#). The injectors are fed by a common fuel rail as part of a 'returnless' fuel system. The fuel rail pressure is regulated to 4.5 bar by a fuel pressure regulator which is integral to the fuel pump module, within the fuel tank. The injectors can be checked by resistance checks. There is a fuel pressure test Schrader valve attached to the fuel rail on the front LH side for fuel pressure testing purposes. The [ECM](#) monitors the output power stages of the injector drivers for electrical faults.

The injectors have a resistance of 13.8 Ohms ± 0.7 Ohms @ 20 Degrees Celsius.

Ignition Coils

E47306

The engine is fitted with six plug-top coils that are driven directly by the [ECM](#). This means that the [ECM](#), at the point where sufficient charge has built up, switches the primary circuit of each coil and a spark is produced in the spark plug. The positive supply to the coil is fed from a common fuse. Each coil contains a power stage to trigger the primary current. The [ECM](#) sends a signal to each of the coils power stage to trigger the power stage switching. Each bank has a feedback signal that is connected to each power stage. If the coil power stage has a failure the feedback signal is not sent, causing the [ECM](#) to store a fault code appropriate to the failure.

The [ECM](#) calculates the dwell time depending on battery voltage and engine speed to ensure constant secondary energy. This ensures sufficient secondary (spark) energy is always available, without excessive primary current flow thus avoiding overheating or damage to the coils.

The individual cylinder spark timing is calculated from a variety of inputs:

- Engine speed and load.
- Engine temperature.
- Knock control.
- Auto gearbox shift control.
- Idle speed control.

Fuel Rail Pressure Sensor

E58945

The fuel rail pressure sensor is located on top of the fuel rail adjacent to the fuel inlet. The fuel rail pressure sensor measures the pressure of the fuel in the fuel rail. This input is then used by the fuel pump control module to control the amount of fuel delivered to the fuel rail.

Fuel Pump Driver Module

E84483

The [FPDM](#) is located on the RH side of the charcoal canister on top of the fuel tank. The fuel pump control module receives a power supply via the fuel pump relay in the auxiliary fuse box.

The [ECM](#) sends a [PWM](#) signal to the [FPDM](#), the duty cycle of the signal determines the duty cycle of the pump. The [ECM](#) sets a target fuel pressure based on engine load. The target fuel pressure is maintained by using feedback from the fuel rail pressure sensor which is used to control the fuel pump via a closed loop [PWM](#) signal. The [PWM](#) signal to the pump represents half the ON time of the pump. If the [ECM](#) transmits a 50% on time the fuel pump control module drives the pump at 100%. If the [ECM](#) transmits a 5% ON time the fuel pump control module drives the pump at 10%. The fuel pump control module will only turn the fuel pump ON if it receives a valid signal between 4% and 50%. When the [ECM](#) requires the fuel pump to be turned OFF the [ECM](#) transmits a duty cycle signal of 75%.

The status of the [FPDM](#) is monitored by the [ECM](#). Any errors can be retrieved from the [ECM](#). The fuel pump control module cannot be interrogated for diagnostic purposes.

The [ECM](#) controls the [FPDM](#) in response to inputs from the fuel rail pressure sensor, [MAP](#) and the [MAF/IAT](#) sensor.

Variable Valve Timing (VVT)

Variable valve timing is used on the V6 engine to enhance low and high speed engine performance and idle speed quality.

For each intake camshaft the [VVT \(variable valve timing\)](#) system comprises:

- [VVT](#) unit
- Valve timing solenoid

The [VVT](#) system alters the phase of the intake valves relative to the fixed timing of the exhaust valves, to alter:

- The mass of air flow to the cylinders.
- The engine torque response.
- Emissions.

The [VVT](#) unit uses a vane type device to control the camshaft angle. The system operates over a range of 48 degrees and is advanced or retarded to its optimum position within this range.

The [VVT](#) system is controlled by the [ECM](#) based on engine load and speed along with engine oil temperature to calculate the appropriate camshaft position.

The [VVT](#) system provides the following advantages:

- Reduced engine emissions and improved fuel consumption which in turn improves the engines internal [EGR](#) effect over a wider operating range.
- Enhanced full load torque characteristics.
- Improved fuel economy through optimized torque over the engine speed range.

Variable Valve Timing Unit

E62237

ItemDescription

1 Vane housing

2	Vane shaft
3	Retard chamber
4	Rotation direction
5	Advance chamber oil channel
6	Stopper pin
7	Intake camshaft
8	Retard chamber oil channel
9	Advance chamber

The [VVT](#) unit is a hydraulic actuator mounted on the end of the intake camshaft. The unit advances or retards the camshaft timing to alter the camshaft to crankshaft phase. The [ECM](#) controls the [VVT](#) timing unit via an oil control solenoid. The oil control solenoid routes oil pressure to the advance or retard chambers either side of the vanes within the [VVT](#) unit.

The [VVT](#) unit is driven by the primary drive chain and rotates relative to the exhaust camshaft. When the [ECM](#) requests a retard in camshaft timing the oil control solenoid is energized which moves the shuttle valve in the solenoid to the relevant position allowing oil pressure to flow out of the advance chambers in the [VVT](#) unit whilst simultaneously allowing oil pressure into the retard chambers.

The [ECM](#) controls the advancing and retarding of the [VVT](#) unit based on engine load and speed. The [ECM](#) sends an energize signal to the oil control solenoid until the desired [VVT](#) position is achieved. When the desired [VVT](#) position is reached, the energizing signal is reduced to hold the oil control solenoid position and consequently desired [VVT](#) position. This function is under closed loop control and the [ECM](#) can sense any variance in shuttle valve oil pressure via the camshaft position sensor and can adjust the energizing signal to maintain the shuttle valve hold position.

operation can be affected by engine oil temperature and properties. At very low oil temperatures the movement of the [VVT](#) mechanism will be slow due to the high viscosity of the oil. While at high oil temperatures the low oil viscosity may impair the [VVT](#) operation at low oil pressures. The oil pump has the capacity to cope with these variations in oil pressure while an oil temperature sensor is monitored by the [ECM](#) to provide oil temperature feedback. At extremely high oil temperatures the [ECM](#) may limit the amount of [VVT](#) advance in order to prevent the engine from stalling when returning to idle speed.

[VVT](#) does not operate when engine oil pressure is below 1.25 bar. This is because there is insufficient pressure to release the [VVT](#) units internal stopper pin. This occurs when the engine is shut down and the [VVT](#) unit has returned to the retarded position. The stopper pin locks the [VVT](#) unit to the camshaft to ensure camshaft stability during the next start up.

Valve Timing Solenoid

E47302

Valve Timing Solenoid

The valve timing solenoid controls the position of the shuttle valve in the bush carrier. A plunger on the solenoid extends when the solenoid is energized and retracts when the solenoid is de-energized.

When the valve timing solenoids are de-energized, the coil springs in the bush carriers position the shuttle valves to connect the valve timing units to drain. In the valve timing units, the return springs hold the ring pistons and gears in the retarded position. When the valve timing solenoids are energized by the [ECM](#), the solenoid plungers position the shuttle valves to direct engine oil to the valve timing units. In the valve timing units, the oil pressure overcomes the force of the return springs and moves the gears and ring pistons to the advanced position. System response times are 1.0 second maximum for advancing and 0.7 second maximum for retarding. While the valve timing is in the retarded mode, the [ECM](#) produces a periodic lubrication pulse. This momentarily energizes the valve timing solenoids to allow a spurt of oil into the valve timing units. The lubrication pulse occurs once every 5 minutes.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Electronic Engine Controls

Diagnosis and Testing

Principles of Operation

For a detailed description of the 4.2L petrol electronic engine controls, refer to the relevant Description and Operation section in the workshop manual. REFER to: (303-14 Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• **NOTE:** If the module or a component is suspect and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the Check and installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B10A231	Crash Input	<ul style="list-style-type: none"> No signal 	Refer to the electrical circuit diagrams and check RCM PWM signal circuit for short, open circuit
B11DB01	Battery Monitoring Module	<ul style="list-style-type: none"> Battery monitoring system hardware fault 	Disconnect vehicle battery, re-connect after 60 seconds, clear DTC and retest. If DTC remains Check and install a new battery monitoring module
B11DB87	Battery Monitoring Module	<ul style="list-style-type: none"> Battery monitoring module connector dis-connected/poor connection Battery monitoring module to RJB LIN circuit - open circuit Battery monitoring module to battery positive monitor circuit - open circuit Battery monitoring module/RJB failure 	If additional DTCs B108783, B108786, B108787 are logged, suspect the RJB. Check and Check and install a new RJB as required, refer to the new module/component Check and installation note at the top of the DTC Index. If additional DTCs B108783, B108786, B108787 are NOT logged, check for good/clean contact at battery monitoring module connector, refer to electrical circuit diagrams and check battery monitoring module to RJB LIN circuit and battery monitoring module to battery positive monitor circuit for open circuit. Clear DTC and repeat automated diagnostic procedure using manufacturer approved diagnostic system. If DTC remains suspect the battery monitoring module, check and Check and install a new battery monitoring module as required, refer to the new module/component Check and installation note at the top of the DTC Index

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Powertrain Control Module (PCM) Long Drive Cycle Self-Test

General Procedures

WARNING: Where possible, all road tests should be on well surfaced and dry roads. Always comply with speed limits and local traffic regulations.

- **NOTE:** This procedure is an overcheck only. If fault codes are found, interrogation of the relevant system must be carried out and claimed against.
- **NOTE:** The vehicle must exceed 50mph (80 km/h) during the road test.

1. Connect the diagnostic equipment to the vehicle.
2. Follow on screen prompts and check for engine management fault codes.
3. Clear the fault codes following the on screen procedure.
4. Disconnect the diagnostic equipment from the vehicle.
5. **NOTE:** Make sure cruise control is not engaged.

Make sure the engine temperature is above 60 °C (140 °F).

Carry out a road test and perform the following operations.

1. Accelerate to 55 mph (88 km/h) in 5th gear and cruise for 2 minutes with the engine speed at or above 1800rpm.
 2. Lift off the throttle and allow the vehicle to decelerate until the engine speed is less than 1000 rpm.
 3. Stop the vehicle.
 4. Release brake, allow the vehicle to move with no throttle for 1 minute.
 5. Road test is now complete.
6. Connect the diagnostic equipment to the vehicle.
 7. **NOTE:** If fault codes are found, interrogation of the relevant system must be carried out and claimed against.

Follow on screen prompts and check for engine management fault codes.
 8. Disconnect the diagnostic equipment from the vehicle.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Powertrain Control Module (PCM) Short Drive Cycle Self-Test

General Procedures

• NOTE: This procedure is an overcheck only. If fault codes are found, interrogation of the relevant system must be carried out and claimed against.

1. Connect the diagnostic equipment to the vehicle.
2. Follow on screen prompts and check for engine management fault codes.
3. Clear the fault codes following the on screen procedure.
4. Start the engine.
 - Allow the engine to idle for 30 seconds.
 - Raise the engine speed to 1500 rpm and hold for 3 minutes until a temperature of 70°C (158 °F) is achieved.
 - Allow the engine to idle for 30 seconds.
 - Switch off the engine.

5. NOTE: If fault codes are found, interrogation of the relevant system must be carried out and claimed against.

Follow on screen prompts and check for engine management fault codes.

6. Disconnect the diagnostic equipment from the vehicle.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Camshaft Position (CMP) Sensor LH

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the engine cover.
For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
3. Disconnect the camshaft position (CMP) sensor electrical connector.

4. Release the CMP sensor electrical connector.

5. Remove the CMP sensor.
 - Remove the Torx bolt.
 - Remove and discard the O-ring seal.

Installation

1. Install is the reverse of removal.

2. Tighten to 7 Nm.

- Install a new O-ring seal.

E64155

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Camshaft Position (CMP) Sensor RH

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the engine cover.
For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
3. Disconnect the camshaft position (CMP) sensor electrical connector.

E64151

4. Remove the CMP sensor.
 - Remove and discard the O-ring seals.

Installation

1. To install, reverse the removal procedure.
2. Tighten to 7 Nm.
 - Install the new O-ring seals.

E64152

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Catalyst Monitor Sensor

Removal and Installation

General Equipment

Snap-on tool S6176

Removal

1. Raise and support the vehicle.
For additional information, refer to Section [100-02 Jacking and Lifting](#).
2. Disconnect the catalyst monitor sensor.

3.  **CAUTION:** Make sure the wiring harness is not twisted or damaged on removal. Failure to follow this instruction may result in damage to the vehicle.

Using the Snap-on tool S6176, remove the catalyst monitor sensor.

Installation

1.  **CAUTION:** Make sure the wiring harness is not twisted or damaged on installation. Failure to follow this instruction may result in damage to the vehicle.

To install, reverse the removal procedure.

- Tighten to 45 Nm.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Crankshaft Position (CKP) Sensor

4.2L NA V8 - AJV8
Removal and Installation

Removal

WARNING: Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

1. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
2. Disconnect the crankshaft position (CKP) sensor electrical connector.

3. Remove the CKP sensor.

Installation

1. Install is the reverse of removal.
 - Tighten to 7 Nm.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Engine Control Module (ECM)

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the cowl vent screen.
For additional information, refer to: [Cowl Vent Screen](#) (501-02 Front End Body Panels, Removal and Installation).
3. Remove the secondary bulkhead LH panel.
For additional information, refer to: [Secondary Bulkhead Panel LH - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8](#) (501-02 Front End Body Panels, Removal and Installation).
4. Remove the engine compartment brace.

5. Release the pedestrian protection actuator bracket.

6. Remove the pedestrian protection actuator.

7. Reposition the pedestrian protection actuator bracket.

8. Remove the engine control module (ECM) cover.

9. Remove the ECM.

Installation

1. Install is the reverse of removal.
2. Tighten to 10 Nm.

3. Tighten to 6 Nm.

4. Tighten to 8 Nm.

5. Tighten to 25 Nm.

6. Tighten to 25 Nm.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Engine Coolant Temperature (ECT) Sensor

Removal and Installation

Removal

• WARNINGS:

 Never remove the coolant pressure cap under any circumstances while the engine is operating. Failure to follow this instruction may result in personal injury.

 To avoid having scalding hot coolant or steam blowing out of the cooling system, use extreme care when removing the coolant pressure cap from a hot cooling system. Wait until the engine has cooled, then wrap a thick cloth around the coolant pressure cap and turn it slowly until the pressure begins to release. Step back while the pressure is released from the system. When certain all the pressure has been released (still with a cloth) turn and remove the coolant pressure cap from the coolant expansion tank. Failure to follow these instructions may result in personal injury.

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2.  **WARNING:** Make sure to support the vehicle with axle stands.

Raise and support the vehicle.
3. Drain the cooling system.
For additional information, refer to: Cooling System Draining, Filling and Bleeding (303-03, General Procedures).
4. Remove the throttle body.
For additional information, refer to: [Throttle Body](#) (303-04A Fuel Charging and Controls - 4.2L NA V8 - AJV8, Removal and Installation).
5. Remove the engine coolant temperature (ECT) sensor.
 - Remove the retaining clip.
 - Remove and discard the O-rings.

E63440

Installation

1. Install is the reverse of removal.
 - Fill the cooling system up to the MAX mark on the coolant expansion tank using a fifty percent mixture of Jaguar Premium Cooling System Fluid or equivalent, meeting Jaguar specification WSS M97B44-D and fifty percent water.

E63440

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Fuel Temperature Sensor

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the engine cover.
For additional information, refer to: [Engine Cover - 4.2L NA V8 - AJV8](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).

 **WARNING:** The spilling of fuel is unavoidable during this operation. Ensure that all necessary precautions are taken to prevent fire and explosion.

 **CAUTION:** Always plug any open connections to prevent contamination.

Remove the fuel temperature sensor.

- Disconnect the electrical connector.
- Position an absorbent cloth to collect fluid spillage.

E64000

Installation

 **WARNING:** After carrying out repairs, the fuel system must be checked visually for leaks. Failure to follow this instruction may result in personal injury.

Install is the reverse of removal.

- Tighten to 7 Nm.
- Clean the components.

E64000

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Heated Oxygen Sensor (HO2S)

Removal and Installation

General Equipment

Snap-on tool S6176

Removal

1.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

2. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
3. Disconnect the heated oxygen sensor (HO2S) electrical connector.

4.  **CAUTION:** Make sure the HO2S wiring harness is not twisted more than 180 degrees and is not in contact with either the exhaust or driveshaft.

Remove the HO2S.

- Using the Snap-on tool S6176, remove the HO2S.

Installation

1.  **WARNING:** Make sure the HO2S wiring harness is not twisted more than 180 degrees and is not in contact with the exhaust.

Install is the reverse of removal.

- Tighten to 45 Nm.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Intake Air Temperature (IAT) Sensor

Removal and Installation

Removal

1. Remove the air temperature sensor.
 - Remove and discard the O-ring seal.

Installation

1. Install is the reverse of removal.
 - Tighten to 3 Nm.

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Knock Sensor (KS)

Removal and Installation

Removal

1. Remove the intake manifold assembly.
For additional information, refer to: [Intake Manifold](#) (303-01A Engine - 4.2L NA V8 - AJV8, In-vehicle Repair).
2. NOTE: LH illustration shown, RH is similar.

Remove the knock sensor.

- Remove the knock sensor.

Installation

1. NOTE: LH illustration shown, RH is similar.

To install, reverse the removal procedure.

- Tighten to 25 Nm

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Manifold Absolute Pressure (MAP) Sensor

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the intake manifold.
For additional information, refer to: [Intake Manifold](#) (303-01A Engine - 4.2L NA V8 - AJV8, In-vehicle Repair).
3. Remove the manifold absolute pressure (MAP) sensor.
 - Remove and discard the MAP sensor O-ring seal.

VUJ0005611

Installation

1. Install is the reverse of removal.
2. Tighten to 10 Nm.
 - Install a new MAP sensor O-ring seal.

VUJ0005611

3. NOTE: For NAS vehicles only.

If required, carry out a short drive cycle.
For additional information, refer to: Powertrain Control Module (PCM) Short Drive Cycle Self-Test (303-14C, General Procedures).

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Mass Air Flow (MAF) Sensor

Removal and Installation

Removal

1. Remove the mass air flow (MAF) sensor.
 - Remove and discard the O-ring seal.

VUJ0005601

Installation

1. To install, reverse the removal procedure.
 - Tighten to 3 Nm.

VUJ0005601

2. **NOTE:** For NAS vehicles only.

If required, carry out a short drive cycle.
For additional information, refer to: Powertrain Control Module (PCM) Short Drive Cycle Self-Test (303-14C, General Procedures).

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Oil Temperature Sensor

Removal and Installation

Removal

1. Raise and support the vehicle.
2. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
3. Disconnect the oil temperature sensor electrical connector.

E30424

4. Remove the oil temperature sensor.

E31009

Installation

1. **NOTE:** Apply a small bead of sealant meeting Jaguar specification on the first three threads of the oil temperature sensor.

To install, reverse the removal procedure.

- Tighten to 15 Nm.

E31009

Electronic Engine Controls - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Variable Camshaft Timing (VCT) Oil Control Solenoid

Removal and Installation

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Remove the valve cover.
For additional information, refer to: [Valve Cover LH](#) (303-01A Engine - 4.2L NA V8 - AJV8, In-vehicle Repair).
3. **NOTE:** Left-hand shown, right-hand similar.

Remove the variable camshaft timing (VCT) oil control solenoid.

Installation

1. To install, reverse the removal procedure.
 - Tighten to 10 Nm.

2. **NOTE:** For NAS vehicles only.

If required, carry out a short drive cycle.
For additional information, refer to: Powertrain Control Module (PCM) Short Drive Cycle Self-Test (303-14C, General Procedures).

Description Vehicles With: ZF 6HP26 - Overview

Description and Operation

OVERVIEW

The ZF 6HP26 transmission is an electronically controlled, six speed unit. The transmission is manufactured by ZF Transmissions GmbH in Saarbrücken, Germany.

This transmission represents the latest in automatic transmission technology and incorporates new features to enhance the transmission functionality:

- The hydraulic and electronic control elements of the transmission, including the [TCM \(transmission control module\)](#), are incorporated in a single unit located inside the transmission and is known as 'Mechatronic'
- Another new strategy is Adaptive Shift Strategy (ASIS). ASIS represents the continuous adaptation of shift changes to suit the driving style of the driver which can vary from sporting to economical.

On supercharged models, the transmission used is an uprated derivative of the 6HP26 transmission used in the 4.2L naturally aspirated model. The uprated transmission includes additional clutch plates to enable the transmission to manage the additional power output of the supercharged engine.

The 6HP26 transmission has the following features:

- Designed to be maintenance free
- Transmission fluid is 'fill for life'
- The torque converter features a controlled slip feature with electronically regulated control of lock-up, creating a smooth transition to the fully locked condition
- Shift programs controlled by the [TCM](#)
- Connected to the [ECM \(engine control module\)](#) via the High Speed [CAN \(controller area network\)](#) bus for communications
- Uses a High Speed [CAN](#) bus and a 'K' Line (early build vehicles only) connection to the diagnostic socket for diagnostic connection
- Default mode if major faults occur
- Diagnostics available from the [TCM](#) via the high speed [CAN](#) bus.

The gearbox comprises the main casing which houses all of the transmission components. The main case also incorporates an integral bell housing. A fluid pan is bolted to the lower face of the main case and is secured with bolts. The fluid pan is sealed to the main case with a gasket. Removal of the fluid pan allows access to the Mechatronic valve block. The fluid pan has a magnet located around the drain plug which collects any metallic particles present in the transmission fluid. A fluid filter is located inside the fluid pan. If the transmission fluid becomes contaminated or after any service work, the fluid pan with integral filter must be replaced.

The integral bell housing provides protection for the torque converter assembly and also provides the attachment for the gearbox to the engine cylinder block. The torque converter is a non-serviceable assembly which also contains the lock-up clutch mechanism.

The torque converter drives a crescent type pump via drive tangs. The fluid pump is located in the main case, behind the torque converter.

The main case contains the following major components:

- Input shaft
- Output shaft
- Mechatronic valve block which contains the solenoids, speed sensors and the [TCM](#)
- Three rotating multiplate drive clutches
- Two fixed multiplate brake clutches
- A single planetary gear train and a double planetary gear train.

Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission

Description Vehicles With: ZF 6HP26 - System Operation and Component Description

Description and Operation

System Operation

POWER FLOWS

Operation of the transmission is controlled by the **TCM (transmission control module)** which electrically activates various solenoids to control the transmission gear selection. The sequence of solenoid activation is based on programmed information in the **TCM** memory and physical transmission operating conditions such as vehicle speed, throttle position, engine load and JaguarDrive selector position.

ItemDescription

1	Torque input from engine
2	Torque converter lock-up clutch
3	Single web planetary gear carrier
4	Single web planetary gears
5	Single web sunwheel 1
6	Double web sunwheel 2
7	Double web planetary gears - Long
8	Double web planetary gear carrier
9	Double web planetary gears - Short
10	Double web sunwheel 3
11	Torque output from transmission
A	Multiplate clutch
B	Multiplate clutch
C	Multiplate brake
D	Multiplate brake
E	Multiplate clutch

Engine torque is transferred, via operation of single or combinations of clutches to the 2 planetary gear trains. Both gear trains are controlled by reactionary inputs from brake clutches to produce the 6 forward gears and 1 reverse gear. The ratios are as follows:

Gear	1st	2nd	3rd	4th	5th	6th	Reverse
Ratio	4.171	2.340	1.521	1.143	0.867	0.691	3.403

The following table shows which solenoids are activated to produce the required torque output from the transmission.

Electronic Transmission Selector Position	Shift Control Solenoid Valve	Electronic Pressure Regulator Solenoids (EPRS)					
		1	2	3	4	5	6
P	-	-	-	-	ON	-ON-	-
R	-	-	ON	-	ON	-ON-	-

Electronic Transmission Selector Position	Shift Control Solenoid Valve	Electronic Pressure Regulator Solenoids (EPRS)

16	Sunwheel 3

17 Double web planetary gear carrier

18 Planetary gears - short

19 Single web planetary gear carrier

20 Sunwheel 1

The shift elements are 3 rotating multiplate clutches (A, B and E) and 2 fixed multiplate brakes © and D). All shifts from 1st to 6th gears are power-on overlapping shifts. Overlapping shifts can be described as one of the clutches continuing to transmit drive at a lower main pressure until the next required clutch is able to accept the input torque.

The shift elements, clutches and brakes are actuated hydraulically. Fluid pressure is applied to the required clutch and/or brake, pressing the plates together and allowing drive to be transmitted through the plates. The purpose of the shift elements is to perform power-on shifts with no interruption to traction and smooth transition between gear ratios.

POWER FLOW 1st GEAR

The JaguarDrive selector and the selector valve spool are in the 'D' position. Engine torque is transmitted from the torque converter turbine shaft to the ring gear 1 of the single web planetary gear train and the outer plate carrier of clutch 'E'.

Ring gear 1 drives the planetary gears which rotate around sunwheel 1. This drives the planetary gear carrier 1 and also the outer plate carrier of clutch 'A' and the inner plate carrier of clutch 'B'.

When clutch 'A' is engaged, sunwheel 3 in the double web planetary gear train is driven and meshes with the short planetary gears.

The double web planetary gear train is locked against the transmission housing by brake 'D'. This allows ring gear 2 (output shaft) to be driven in the same direction as the engine via the long planetary gears.

- NOTE: Refer to 'Shift Elements' illustration for key

E42721

POWER FLOW 2nd GEAR

E42722

The JaguarDrive selector and the selector spool valve are in the 'D' position. Engine torque is transmitted from the torque converter turbine shaft to the ring gear 1 of the single web planetary gear train and the outer plate carrier of clutch 'E'.

Ring gear 1 drives the planetary gears which rotate around sunwheel 1. This drives the planetary gear carrier 1 and also the outer plate carrier of clutch 'A' and the inner plate carrier of clutch 'B'.

When clutch 'A' is engaged, sunwheel 3 in the double web planetary gear train is driven and meshes with the short planetary gears.

Sunwheel 2 is locked to the transmission housing by brake clutch 'C'. The long planetary gears, which are also meshed with the short planetary gears, roll around the fixed sunwheel 2 and transmit drive to the double web planetary gear train carrier and ring gear 2 in the direction of engine rotation.

• NOTE: Refer to 'Shift Elements' illustration for key

E42723

POWER FLOW 3rd GEAR

E 42724

The JaguarDrive selector and the selector spool valve are in the 'D' position. Engine torque is transmitted from the torque converter turbine shaft to the ring gear 1 of the single web planetary gear train and the outer plate carrier of clutch 'E'.

Ring gear 1 drives the planetary gears which rotate around sunwheel 1. This drives the planetary gear carrier 1 and also the outer plate carrier of clutch 'A' and the inner plate carrier of clutch 'B'.

When clutch 'A' is engaged, sunwheel 3 in the double web planetary gear train is driven and meshes with the short planetary gears.

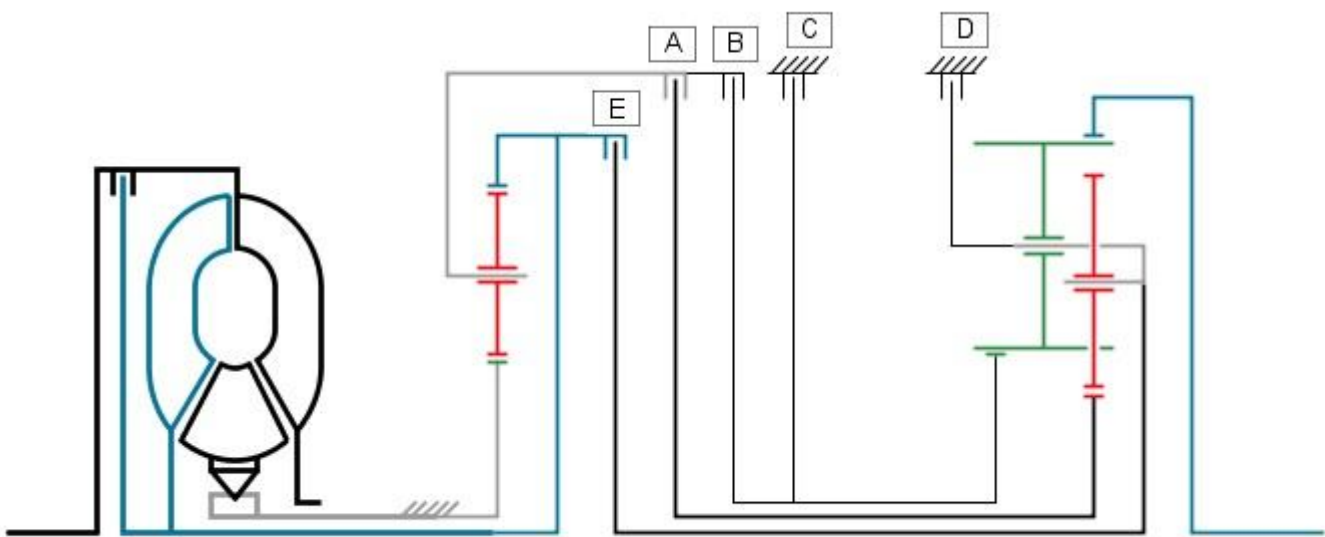

Sunwheel 2 is driven via clutch 'B' which is engaged. The long planetary gears, which are also meshed with the short planetary gears, cannot roll around the fixed sunwheel 2 and therefore transmit drive to the locked double web planetary gear train carrier in the direction of engine rotation.

• NOTE: Refer to 'Shift Elements' illustration for key

E42725

POWER FLOW 4th GEAR

E42726

The JaguarDrive selector and the selector spool valve are in the 'D' position. Engine torque is transmitted from the torque converter turbine shaft to ring gear 1 of the single web planetary gear train and the outer plate carrier of clutch 'E'.

Ring gear 1 drives the planetary gears which rotate around sunwheel 1. This drives the planetary gear carrier 1 and also the outer plate carrier of clutch 'A' and the inner plate carrier of clutch 'B'.

When clutch 'A' is engaged, sunwheel 3 in the double web planetary gear train is driven and meshes with the short planetary gears.

The double web planetary gear carrier is driven via clutch 'E' which is engaged. The long planetary gears, which are also meshed with the short planetary gears and the double web planetary gear carrier, drive ring gear 2 in the direction of engine rotation.

• NOTE: Refer to 'Shift Elements' illustration for key

E42727

POWER FLOW 5th GEAR

E42728

The JaguarDrive selector and the selector spool valve are in the 'D' position. Engine torque is transmitted from the torque converter turbine shaft to ring gear 1 of the single web planetary gear train and the outer plate carrier of clutch 'E'.

Ring gear 1 drives the planetary gears which rotate around sunwheel 1. This drives the planetary gear carrier 1 and also the outer plate carrier of clutch 'A' and the inner plate carrier of clutch 'B'.

When clutch 'A' is engaged, sunwheel 3 in the double web planetary gear train is driven and meshes with the short planetary gears.

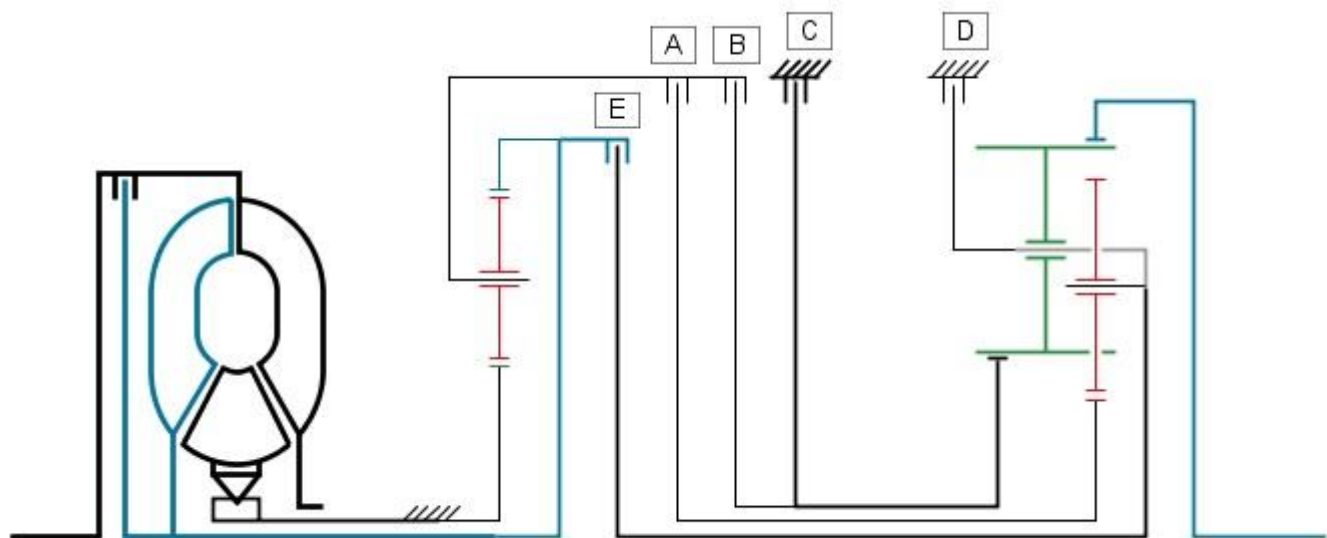

The long planetary gears, which are also meshed with the short planetary gears and the double web planetary gear carrier, drive ring gear 2 in the direction of engine rotation.

• NOTE: Refer to 'Shift Elements' illustration for key

E42729

POWER FLOW 6th GEAR

E42730

The JaguarDrive selector and the selector spool valve are in the 'D' position. Engine torque is transmitted from the torque converter turbine shaft to ring gear 1 of the single web planetary gear train and the outer plate carrier of clutch 'E'.

Clutches 'A' and 'B' are released, removing the effect of the single web planetary gear train.

Clutch brake 'C' is applied which locks sunwheel 2 to the transmission housing.

Clutch 'E' is engaged and drives the double web planetary gear carrier. This causes the long planetary gears to rotate around the fixed sunwheel 2 and transmit drive to ring gear 2 which is driven in the direction of engine rotation.

• NOTE: Refer to 'Shift Elements' illustration for key

E42731

POWER FLOW REVERSE GEAR

E42732

The JaguarDrive selector and the selector spool valve are in the 'R' position. Engine torque is transmitted from the torque converter turbine shaft to ring gear 1 of the single web planetary gear train and the outer plate carrier of clutch 'E'.

Ring gear 1 drives the planetary gears of the single web planetary gear train which rotate around the fixed sunwheel 1. This transmits the drive to the single web planetary gear carrier, the outer plate carrier of clutch 'A' and the inner plate carrier of clutch 'B'.

With clutch 'B' applied, sunwheel 2 in the double web planetary gear train is driven and meshes with the long planetary gears.

The double web planetary gear carrier is locked to the transmission housing by brake clutch 'D'. This allows ring gear 2 to be driven in the opposite direction to engine rotation by the long planetary gears.

• NOTE: Refer to 'Shift Elements' illustration for key

E42733

INSTRUMENT CLUSTER

E95414

ItemDescription

1	Transmission selected gear status
2	Malfunction Indicator Lamp (MIL)
3	Message center

The instrument cluster is connected to the [TCM](#) via the high speed [CAN \(controller area network\)](#) bus. Transmission status is transmitted by the [TCM](#) and displayed to the driver in one of 2 displays in the instrument cluster.

Refer to: [Information and Message Center](#) (413-08 Information and Message Center, Description and Operation).

Malfunction Indicator Lamp (MIL)

The [MIL \(malfunction indicator lamp\)](#) is located in the tachometer in the instrument cluster. Transmission related faults which may affect the vehicle emissions output will illuminate the [MIL](#).

The [MIL](#) is illuminated by the [ECM \(engine control module\)](#) on receipt of a relevant fault message from the [TCM](#) on the high speed [CAN](#). The nature of the fault can be diagnosed using a Jaguar approved diagnostic system which reads the fault codes stored in the [TCM](#) memory.

Transmission Status Display

The transmission status display is located in a [LCD \(liquid crystal display\)](#) at the top of the instrument cluster, between the speedometer and the tachometer. The [LCD](#) shows the JaguarDrive selector position or the selected gear when in manual 'Jaguar Sequential Shift' mode.

The following table shows the displays and their descriptions.

Symbol	Description
P	Park selected
R	Reverse selected
N	Neutral selected
D	Drive selected
S	Sport mode selected
1	1st gear selected (Manual 'Jaguar Sequential Shift' mode)
2	2nd gear selected (Manual 'Jaguar Sequential Shift' mode)
3	3rd gear selected (Manual 'Jaguar Sequential Shift' mode)
4	4th gear selected (Manual 'Jaguar Sequential Shift' mode)
5	5th gear selected (Manual 'Jaguar Sequential Shift' mode)
6	6th gear selected (Manual 'Jaguar Sequential Shift' mode)

Message Center Display

The message center is located in the lower center of the instrument cluster. The message center is a [LCD](#) to relay vehicle status and operating information to the driver and can display messages relating to a number of the vehicle systems. If a transmission fault occurs, the message center will display the message 'GEARBOX FAULT'.

TRANSMISSION CONTROL MODULE (TCM)

The [TCM](#) is an integral part of the Mechatronic valve block which is located at the bottom of the transmission, within the fluid pan. The [TCM](#) is the main controlling component of the transmission.

The [TCM](#) processes signals from the transmission speed and temperature sensors, [ECM](#) and other vehicle systems. From the received signal inputs and pre-programmed data, the [TCM](#) calculates the correct gear, torque converter clutch setting and optimum pressure settings for gear shift and lock-up clutch control.

The [TCM](#) outputs signals to control the shift control solenoid valve and the Electronic Pressure Regulator Solenoids (EPRS) to control the hydraulic operation of the transmission.

The [ECM](#) supplies the engine management data on the high speed [CAN](#) bus system. The [TCM](#) requires engine data to efficiently control the transmission operation, for example; flywheel torque, engine speed, accelerator pedal angle, engine temperature etc.

The steering angle sensor and the [ABS \(anti-lock brake system\)](#) module also supply data to the [TCM](#) on the high speed [CAN](#) bus system. The [TCM](#) uses data from these systems to suspend gear changes when the vehicle is cornering and/or the [ABS](#) module is controlling braking or traction control.

The Mechatronic valve block also contains the speed and temperature sensors. These are integral with the Mechatronic valve block and cannot be serviced individually. The speed sensors measure the transmission input and output speeds and pass signals to the [TCM](#). The fluid temperature sensor is also located in the valve block and measures the fluid temperature of the transmission fluid in the fluid pan.

CONTROLLER AREA NETWORK (CAN)

The high speed [CAN](#) bus is used to connect the powertrain modules. The [CAN](#) bus is connected between the following electronic units:

High Speed CAN Bus

- [TCM](#)
- Instrument cluster
- Adaptive Damping Control Module (ADCM) - if fitted
- Steering angle sensor
- Electric park brake module
- Restraints control module
- [ECM](#)
- [ABS](#) module
- Adaptive speed control module - if fitted
- Diagnostic socket.

The [CAN](#) bus allows a fast exchange of data between modules. The [CAN](#) bus comprises 2 wires which are identified as [CAN](#) high (H) and [CAN](#) low (L). The 2 wires are coloured white/blue (H) and white (L) and are twisted together to minimise electromagnetic interference (noise) produced by the [CAN](#) bus messages.

Refer to: [Communications Network](#) (418-00 Module Communications Network, Description and Operation).

In the event of [CAN](#) bus failure, the following symptoms may be observed:

- Transmission operates in default (limp home) mode
- Torque converter lock-up clutch control is disabled (unlocked)
- Gear position indication in instrument cluster message center inoperative (this will also occur with any transmission fault).

DRIVING MODES

There are a number of different driving modes of operation. Some can be selected by the driver and some are

automatically initiated by the [TCM](#) during driving:

- Normal mode (driver selected)
- Sport mode (driver selected)
- Manual ('Jaguar Sequential Shift') mode (driver selected)
- Adaptive Shift Strategy (ASIS) which comprises the following:
 - Cruise mode
 - Hill mode
 - Default (Limp home) mode
 - Reverse lock-out mode
 - Cooling strategy
 - Curve recognition mode
 - Fast off recognition.

Normal Mode

Normal mode is automatically selected by the [TCM](#) on power up. In this mode all automatic and adaptive modes are active. Normal mode uses gear shift and lock-up maps to allow for vehicle operation which offers fuel consumption and emissions or driveability depending on the driving style. If the transmission is operated in sport or manual mode and the JaguarDrive selector is moved to the 'D' position, normal mode is automatically resumed.

Sport mode is selected by moving the JaguarDrive selector to the 'S' position. When the sport mode is first selected, if 6th gear is currently engaged, the [TCM](#) downshifts to 5th provided the correct engine speed parameters are met.

Manual ('Jaguar Sequential Shift') Mode

Manual mode allows the transmission to operate as a semi-automatic 'Jaguar Sequential Shift' unit. The driver can change up and down the 6 forward gears with the freedom of a manual transmission.

Shift maps are provided for manual mode to protect the engine at high engine speeds. The [TCM](#) will automatically change up to a higher gear ratio to prevent engine overspeed and change down to a lower gear ratio to avoid engine labouring and stalling.

When kickdown is requested the [TCM](#) downshifts to the lowest available gear within the allowed engine speed parameters.

When the vehicle is stationary, to drive off, the driver can select 1st , 2nd or 3rd gear. Any other gear selection will be rejected by the [TCM](#).

When driving off, upshifts can be pre-selected by making + selections with the appropriate steering wheel upshift or downshift paddle for the number of upshifts required. The [TCM](#) then automatically performs a corresponding number of upshifts when the appropriate shift points are reached. So, for example, when starting off in 1st gear, if three upshift (+) selections are made in quick succession, the [TCM](#) will automatically change up through the box to 4th gear as the vehicle accelerates, without any further selections being made.

In manual mode a low gear can be selected to provide engine braking for descending a slope without continuous use of the brake pedal. The driver can prepare for the end of the descent by moving the JaguarDrive selector to the 'D' position. The [TCM](#) will maintain the low gear and only revert to automatic shift control when the throttle is opened and vehicle speed increases.

Adaptive Shift Strategy (ASIS)

With the [TCM](#) linked via the [CAN](#) bus to other vehicle systems, signals are received which can allow the [TCM](#) to calculate the way in which the vehicle is being driven. The type of signals include the following:

- Longitudinal and lateral acceleration
- Engine speed
- Engine torque
- Oil temperature
- Accelerator pedal position
- Wheel speed.

Using these signals, additional transmission control can be obtained. The [TCM](#) can calculate when the vehicle is cornering, all wheels are gripping, the driver is braking or if the driver is accelerating. This is the conventional 'Adaptive' transmission control. ASIS uses this system but adds the continuous adaptation of the gear changes to suit the individual driving style of the driver.

Cruise Mode

When speed control is activated, the [TCM](#) receives a cruise active message on the [CAN](#) bus. The [TCM](#) activates a speed control map which prevents locking and unlocking of the torque converter clutch and minimizes up and down shifts.

Hill Mode

Hill mode is initiated by the [TCM](#) when the engine torque, received via [ECM](#) signals on the [CAN](#) bus, exceeds the theoretical load curve for normal operation. The [TCM](#) monitors this signal to determine when the vehicle is travelling up or down a steep gradient.

In hill mode the [TCM](#) adopts one of four shift maps, three uphill and one downhill. The shift map chosen depends on the severity of the slope as determined from the engine signals and the appropriate gear is selected to assist with the ascent or descent.

Hill mode can also be initiated when the vehicle is at very high altitudes or ambient temperatures.

Default (Limp Home) Mode

If a transmission fault is detected by the [TCM](#), the [TCM](#) adopts a limp home mode strategy. 'GEARBOX FAULT' is displayed in the message center and, if the fault has an effect on engine emissions, the [MIL](#) will also be illuminated.

In default mode, P, R and N functions operate normally (if the fault allows these selections) and the [TCM](#) locks the transmission in 3rd or 5th gear to allow the driver to take the vehicle to the nearest dealer. The torque converter lock-up clutch is disabled and reverse lock-out will not function.

If the vehicle is stopped and subsequently restarted in the default mode condition, the [TCM](#) operates normally until the fault which caused the condition is detected again.

If electrical power is lost and the transmission is operating in mechanical limp home mode, the transmission will be electronically locked in the 'P' position when the ignition is off. This can be released mechanically if required by operating the emergency park release lever located in the floor console.

Refer to: [External Controls - Vehicles With: ZF 6HP26](#) (307-05 Automatic Transmission/Transaxle External Controls, Description and Operation).

Reverse Lock-Out Mode

When the vehicle is travelling forwards, selecting reverse could cause transmission damage. To protect against this, reverse gear is prohibited if the vehicle is travelling forwards at a road speed of 5 mph (8 km/h) or higher.

Cooling Strategy

The purpose of the cooling strategy is to reduce engine and transmission temperatures during high load conditions. Under these conditions the engine and transmission may generate excessive heat.

If the transmission fluid temperature increases to 125°C (257°F) or higher, the [TCM](#) employs the cooling strategy. No message is displayed in the message center for transmission overheat.

The strategy uses a specific shift and torque converter lock-up clutch map. This map allows torque converter clutch lock-up and gear shifts to operate outside of their normal operation. This will reduce the engine speed and/or slip in the torque converter, therefore reducing heat generated by the engine and the transmission.

If the transmission fluid temperature increases to 137°C (278°F) or higher, the transmission will use the default (limp home mode). If the temperature exceeds 140°C (284°F), [CAN](#) bus transmission is disabled.

The cooling strategy is cancelled when the transmission fluid temperature decreases to less than 120°C (248°F) or below.

Curve Recognition

Curve recognition is activated when high levels of lateral acceleration and/or steering angle are detected via the [ABS](#) module and steering angle sensor signals on the [CAN](#) bus. When this condition is detected, the [TCM](#) prevents the transmission from changing to a higher gear to assist with cornering. When the vehicle completes its manoeuvre, the transmission will shift to the correct ratio.

Fast Off Recognition

Fast off recognition is activated when the [TCM](#) detects that the driver has backed off the accelerator pedal quickly in a 'change of mind' manoeuvre. This is detected by monitoring for a high level of negative pedal angle from the [ECM](#) signal on the high speed [CAN](#) bus. If this condition is detected, the [TCM](#) holds the current gear ratio to allow the driver to complete his original action without the need for a downshift. The mode remains active for a predetermined time period or if the driving style remains passive.

TRANSMISSION FAULT STATUS

If the [TCM](#) detects a fault with the transmission system, it will enter a default mode to prevent further damage to the transmission and allow the vehicle to be driven.

When a fault is detected a high speed [CAN](#) message is sent from the [TCM](#) and is received by the instrument cluster. The instrument cluster illuminates the [MIL](#) if an emissions related fault occurs and displays 'GEARBOX FAULT' in the message center.

Some transmission faults may not illuminate the [MIL](#) or display a fault message, but the driver may notice a reduction in shift quality.

ENGINE SPEED AND TORQUE MONITORING

The [ECM](#) constantly supplies the [TCM](#) with information on engine speed and torque through messages on the high speed [CAN](#) bus. The [TCM](#) uses this information to calculate the correct and appropriate timing of shift changes.

If the messages are not received by the [ECM](#), the [TCM](#) will implement a back-up strategy to protect the transmission from damage and allow the vehicle to be driven.

In the event of an engine speed or torque signal failure, the transmission will adopt the electrical limp home mode with the transmission operating in a fixed gear.

TOWING FOR RECOVERY

The following procedure must be used to ensure that the vehicle is towed in a safe condition and damage to the vehicle transmission systems is prevented.

- Secure the towing attachment from the recovery vehicle to the towing eye of the vehicle to be recovered.
- Make sure that the parking brake is on. Press the start/stop button to switch the ignition on.
- Apply the footbrake and move the JaguarDrive selector to the neutral position. If electrical power is not available, use the emergency park release lever to select neutral.
Refer to: [External Controls - Vehicles With: ZF 6HP26](#) (307-05 Automatic Transmission/Transaxle External Controls, Description and Operation).
- Make sure that the Smart Key is placed in the start control module to ensure that the electric steering lock is disengaged and, if the stop lamps and turn signal indicators are required, the start/stop button is pressed and the

ignition is on.

- Make sure that the parking brake is released before the vehicle is towed.
- The vehicle can only be towed for a maximum of 0.5 miles (0.8 km) at a maximum speed of 30 mph (48 km/h).

WARNING: Do not remove the Smart Key from the vehicle when the vehicle is being towed. The electric steering lock will be engaged preventing the steering from being turned.

With the engine not running, the brake booster and power steering pump will be inoperative. Care must be taken to ensure the vehicle is manoeuvred and driven accordingly.

Component Description

ZF 6HP26 Automatic Transmission – Exploded View

15	Input shaft seal
16	Torque converter

The transmission comprises the main casing which houses all of the transmission components. The main case also incorporates an integral bell housing.

A fluid pan is attached to the lower face of the main case and is secured with bolts. The fluid pan is sealed to the main case with a gasket. Removal of the fluid pan allows access to the Mechatronic valve block. The fluid pan has a magnet located around the drain plug which collects any metallic particles present in the transmission fluid.

A fluid filter is located inside the fluid pan. If the transmission fluid becomes contaminated or after any service work, the fluid pan with integral filter must be replaced.

The integral bell housing provides protection for the torque converter assembly and also provides the attachment for the gearbox to the engine cylinder block. The torque converter is a non-serviceable assembly which also contains the lock-up clutch mechanism. The torque converter drives a crescent type pump via drive tangs. The fluid pump is located in the main case, behind the torque converter.

The main case contains the following major components:

- Input shaft
- Output shaft
- Mechatronic valve block which contains the solenoids, speed sensors and the [TCM](#)
- 3 rotating multiplate drive clutches
- 2 fixed multiplate brake clutches
- A single planetary gear train and a double planetary gear train.

11	Lock-up clutch piston
12	Lock-up clutch plate

The torque converter is the coupling element between the engine and the transmission and is located in the bell housing, on the engine side of the transmission. The driven power from the engine crankshaft is transmitted hydraulically and mechanically through the torque converter to the transmission. The torque converter is connected to the engine by a drive plate.

The torque converter comprises an impeller, a stator and a turbine. The torque converter is a sealed unit with all

components located between the converter housing cover and the impeller. The two components are welded together to form a sealed, fluid filled housing. With the impeller welded to the converter housing cover, the impeller is therefore driven at engine crankshaft speed.

The converter housing cover has 4 threaded bosses which provide for attachment of the engine drive plate which is connected to the engine crankshaft. The threaded bosses also provide for location of special tools which are required to remove the torque converter from the bell housing.

Impeller

Fluid Flow

E42397

ItemDescription

1	Turbine
2	Stator
3	Impeller

When the engine is running the rotating impeller acts as a centrifugal pump, picking up fluid at its center and discharging it at high velocity through the blades on its outer rim. The design and shape of the blades and the curve of the impeller body cause the fluid to rotate in a clockwise direction as it leaves the impeller. This rotation improves the efficiency of the fluid as it contacts the outer row of blades on the turbine.

The centrifugal force of the fluid leaving the blades of the impeller is passed to the curved inner surface of the turbine via the tip of the blades. The velocity and clockwise rotation of the fluid causes the turbine to rotate.

Turbine

The turbine is similar in design to the impeller with a continuous row of blades. Fluid from the impeller enters the turbine through the tip of the blades and is directed around the curved body of the turbine to the root of the blades. The curved surface redirects the fluid back in the opposite direction to which it entered the turbine, effectively increasing the turning force applied to the turbine from the impeller. This principle is known as torque multiplication.

When engine speed increases, turbine speed also increases. The fluid leaving the inner row of the turbine blades is rotated in a counter-clockwise direction due to the curve of the turbine and the shape of the blades. The fluid is now flowing in the opposite direction to the engine rotation and therefore the impeller. If the fluid was allowed to hit the impeller in this condition, it would have the effect of applying a brake to the impeller, eliminating the torque multiplication effect. To prevent this, the stator is located between the impeller and the turbine.

Stator

The stator is located on the splined transmission input shaft via a freewheel clutch. The stator comprises a number of blades which are aligned in an opposite direction to those of the impeller and turbine. The main function of the stator is to redirect the returning fluid from the turbine, changing its direction to that of the impeller.

The redirected fluid from the stator is directed at the inner row of blades of the impeller, assisting the engine in turning the impeller. This sequence increases the force of the fluid emitted from the impeller and thereby increases the torque multiplication effect of the torque converter.

• NOTE: The following illustration shows a typical stator

Stator Functions

E 42398

ItemDescription

1	Blades
2	Stator held – fluid flow redirected
3	Stator rotates freely
4	Roller
5	Converter at coupling speed
6	Fluid flow from turbine
7	Converter multiplying
8	Fluid flow from impeller
9	Drive from engine
10	Impeller
11	Stator
12	Turbine
13	Output to transmission

Refer to the 'Stator Functions' illustration

Fluid emitted from the impeller acts on the turbine. If the turbine is rotating at a slower speed than the fluid from the impeller, the fluid will be deflected by the turbine blades in the path 'A'. The fluid is directed at and deflected by the stator blades from path 'B' to path 'C'. This ensures that the fluid is directed back to the pump in the optimum direction. In this condition the sprag clutch is engaged and the force of the fluid on the stator blades assists the engine in rotating the impeller.

As the rotational speed of the engine and therefore the turbine increases, the direction of the fluid leaving the turbine changes to path 'D'. The fluid is now directed from the turbine to the opposite side of the stator blades, rotating the stator in the opposite direction. To prevent the stator from resisting the smooth flow of the fluid from the turbine, the sprag clutch releases, allowing the stator to rotate freely on its shaft.

When the stator becomes inactive, the torque converter no longer multiplies the engine torque. When the torque converter reaches this operational condition it ceases to multiply the engine torque and acts solely as a fluid coupling, with the impeller and the turbine rotating at approximately the same speed.

The stator uses a sprag type, one way, freewheel clutch. When the stator is rotated in a clockwise direction the sprags twist and are wedged between the inner and outer races. In this condition the sprags transfer the rotation of the outer race to the inner race which rotates at the same speed.

One Way Free Wheel Clutch – Typical

E 42712

ItemDescription

1	Sprags
2	Inner race
3	Outer race
4	Sprag and cage assembly
5	Sprag outer race
6	Sprag inner race
7	Retaining ring

The free wheel clutch can perform three functions; hold the stator stationary, drive the stator and free wheel allowing the stator to rotate without a drive output. The free wheel clutch used in the 6HP26 transmission is of the sprag type and comprises an inner and outer race and a sprag and cage assembly. The inner and outer races are pressed into their related components with which they rotate. The sprag and cage assembly is located between the inner and outer races.

The sprags are located in a cage which is a spring which holds the sprags in the 'wedge' direction and maintains them in contact with the inner and outer races.

Referring to the illustration, the sprags are designed so that the dimension 'B' is larger than the distance between the inner and outer race bearing surfaces. When the outer race rotates in a clockwise direction, the sprags twist and the edges across the dimension 'B' wedge between the races, providing a positive drive through each sprag to the inner race. The dimension 'A' is smaller than the distance between the inner and outer race bearing surfaces. When the outer race rotates in an anti-clockwise direction, the dimension 'A' is too small to allow the sprags to wedge between the races, allowing the outer race to rotate freely.

On the illustration shown, when the outer race is rotated in a clockwise direction, the sprags twist and are 'wedged' between the inner and outer races. The sprags then transfer the rotation of the outer race to the inner race, which rotates at the same speed.

Lock-Up Clutch Mechanism

The Torque Converter Clutch (TCC) is hydraulically controlled by an electronic pressure regulating solenoid (EPRS6) which is controlled by the [TCM](#). This allows the torque converter to have 3 states of operation as follows:

- Fully engaged
- Controlled slip variable engagement
- Fully disengaged.

The TCC is controlled by two hydraulic spool valves located in the valve block. These valves are actuated by pilot pressure supplied via a solenoid valve which is also located in the valve block. The solenoid valve is operated by PWM (pulse width modulation) signals from the [TCM](#) to give full, partial or no lock-up of the torque converter.

E 42399

ItemDescription

A	Unlocked condition
B	Locked condition
1	Clutch plate
2	Clutch piston
3	Torque converter body
4	Turbine
5	Impeller
6	Stator
7	Piston chamber
8	Turbine chamber

The lock-up clutch is a hydro-mechanical device which eliminates torque converter slip, improving fuel consumption. The engagement and disengagement is controlled by the [TCM](#) to allow a certain amount of controlled 'slip'. This allows a small difference in the rotational speeds of the impeller and the turbine which results in improved shift quality. The lock-up clutch comprises a piston and a clutch friction plate.

In the unlocked condition, the oil pressure supplied to the piston chamber and the turbine chamber is equal. Pressurized fluid flows through a drilling in the turbine shaft and through the piston chamber to the turbine chamber. In this condition the clutch plate is held away from the torque converter body and torque converter slip is permitted.

In the locked condition, the TCC spool valves are actuated by the electronic pressure regulating solenoid (EPRS6). The fluid flow in the unlocked condition is reversed and the piston chamber is vented. Pressurized fluid is directed into the turbine chamber and is applied to the clutch piston. The piston moves with the pressure and pushes the clutch plate against the torque converter body. As the pressure increases, the friction between the clutch plate and the body increases, finally resulting in full lock-up of the clutch plate with the body. In this condition there is direct mechanical drive from the engine crankshaft to the transmission planetary gear train.

FLUID PUMP

The fluid pump is an integral part of the transmission. The fluid pump is used to supply hydraulic pressure for the operation of the control valves and clutches, to pass the fluid through the transmission cooler and to lubricate the gears and shafts.

The 6HP26 fluid pump is a crescent type pump and is located between the intermediate plate and the torque converter. The pump has a delivery rate of 16 cm³ per revolution.

E42400

ItemDescription

1	Securing ring
2	Shaft oil seal
3	O-ring seal
4	Pump housing
5	Ring gear
6	Crescent spacer
7	Roller bearing
8	Impeller
9	Centring pin
10	Spring washer
11	Outlet port (high pressure)
12	Inlet port (low pressure)

The pump comprises a housing, a crescent spacer, an impeller and a ring gear. The housing has inlet and outlet ports to direct flow and is located in the intermediate plate by a centring pin. The pump action is achieved by the impeller, ring gear and crescent spacer.

The crescent spacer is fixed in its position by a pin and is located between the ring gear and the impeller. The impeller is driven by drive from the torque converter hub which is located on a needle roller bearing in the pump housing. The impeller teeth mesh with those of the ring gear. When the impeller is rotated, the motion is transferred to the ring gear which rotates in the same direction.

The rotational motion of the ring gear and the impeller collects fluid from the intake port in the spaces between the teeth. When the teeth reach the crescent spacer, the oil is trapped in the spaces between the teeth and is carried with the rotation of the gears. The spacer tapers near the outlet port. This reduces the space between the gear teeth causing a build up of fluid pressure as the oil reaches the outlet port. When the teeth pass the end of the spacer the pressurized fluid is released into the outlet port.

The fluid emerging from the outlet port is passed through the fluid pressure control valve. At high operating speeds the pressure control valve maintains the output pressure to the gearbox at a predetermined maximum level. Excess fluid is relieved from the pressure control valve and is directed, via the main pressure valve in the valve block, back to the pump inlet port. This provides a pressurized feed to the pump inlet which prevents cavitation and reduces pump noise.

MECHATRONIC VALVE BLOCK

The Mechatronic valve block is located in the bottom of the transmission and is covered by the fluid pan. The valve block houses the TCM, electrical actuators, speed sensors and control valves which provide all electro-hydraulic control for all transmission functions. The Mechatronic valve block comprises the following components:

- TCM
- 6 pressure regulator solenoids

- 1 shift control solenoid
- 1 damper
- 21 hydraulic spool valves
- Manually operated selector valve
- Temperature sensor
- Turbine speed sensor
- Output shaft speed sensor.

Electronic Pressure Regulator Solenoids (EPRS)

E42713

Six Electronic Pressure Regulator Solenoids (EPRS) are located in the valve block. The solenoids are controlled by [PWM](#) signals from the [TCM](#). The solenoids convert the electrical signals into hydraulic control pressure proportional to the signal to actuate the spool valves for precise transmission operation.

The following table shows the EPRS and their associated functions:

EPRS	Function
1	Clutch A
2	Clutch B
3	Clutch C
4	Brake clutches D and E
5	System pressure control
6	Torque converter lock-up control

Solenoids EPRS 1, 3 and 6 supply a lower control pressure as the signal amperage increases and can be identified by a black connector cap. The [TCM](#) operates the solenoids using [PWM](#) signals. The [TCM](#) monitors engine load and clutch slip and varies the solenoid duty cycle accordingly. The solenoids have a 12 V operating voltage and a pressure range of 0 - 4.6 bar (0 - 67 lbf.in²).

Solenoids EPRS 2, 4 and 5 supply a higher control pressure as the signal amperage increases and can be identified by a green connector cap. The solenoids are normally open, regulating flow solenoid valves. The [TCM](#) operates the solenoids using a [PWM](#) ground proportional to the required increasing or decreasing clutch pressures. The solenoids have a 12 V operating voltage and a pressure range of 4.6 - 0 bar (67 - 0 lbf.in²).

The resistance of the coil winding for the EPRS solenoids is 5.05 ohms at 20°C (68°F).

Solenoid Valves

E42714

Solenoid Valves (SV) are located in the valve block. The solenoids are controlled by the [TCM](#) and converts electrical signals into hydraulic control signals to control clutch application and park lock cylinder operation.

The control solenoids are open/closed, on/off solenoids which are controlled by the [TCM](#) switching the solenoid to earth. The [TCM](#) also supplies power to the solenoids. The [TCM](#) energises the solenoids in a programmed sequence for clutch application for gear ratio changes, shift control and park lock application.

The resistance of the solenoid coil winding within the solenoid is between 26 to 30.4 ohms at 20°C (68°F).

SENSORS

Speed Sensors

The turbine speed sensor and the output shaft speed sensor are Hall effect type sensors located in the Mechatronic valve block and are not serviceable items. The [TCM](#) monitors the signals from each sensor to determine the input (turbine) speed and the output shaft speed.

The turbine speed is monitored by the [TCM](#) to calculate the slip of the torque converter clutch and internal clutch slip. This signal allows the [TCM](#) to accurately control the slip timing during shifts and adjust clutch application or release pressure for overlap shift control.

The output shaft speed is monitored by the [TCM](#) and compared to engine speed signals received on the [CAN](#) bus from the [ECM](#). Using a comparison of the two signals the [TCM](#) calculates the transmission slip ratio for plausibility and maintains adaptive pressure control.

Temperature Sensor

The temperature sensor is also located in the Mechatronic valve block. The [TCM](#) uses the temperature sensor signals to determine the temperature of the transmission fluid. These signals are used by the [TCM](#) to control the transmission operation to promote faster warm-up in cold conditions or to assist with fluid cooling by controlling the transmission operation when high fluid temperatures are experienced. If the sensor fails, the [TCM](#) will use a default value and a fault code will be stored in the [TCM](#).

DAMPER

There is one damper located in the valve housing. The damper is used to regulate and dampen the regulated pressure supplied via EPRS 5. The damper is load dependent through modulation of the damper against return spring pressure.

The damper comprises a piston, a housing bore and a spring. The piston is subject to the pressure applied by the spring. The bore has a connecting port to the function to which it applies. Fluid pressure applied to the applicable component (i.e. a clutch) is also subjected to the full area of the piston, which moves against the opposing force applied by the spring. The movement of the piston creates an action similar to a shock absorber, momentarily delaying the build up of pressure in the circuit. This results in a more gradual application of clutches improving shift quality.

SPOOL VALVES

The valve block contains 21 spool valves which control various functions of the transmission. The spool valves are of conventional design and are operated by fluid pressure.

Each spool valve is located in its spool bore and held in a default (unpressurized) position by a spring. The spool bore has a number of ports which allow fluid to flow to other valves and clutches to enable transmission operation. Each spool has a piston which is waisted to allow fluid to be diverted into the applicable ports when the valve is operated.

When fluid pressure moves a spool, one or more ports in the spool bore are covered or uncovered. Fluid is prevented from flowing or is allowed to flow around the applicable waisted area of the spool and into another uncovered port. The fluid is either passed through galleries to actuate another spool, operate a clutch or is returned to the fluid pan.

DRIVE CLUTCHES

Multiplate Drive or Brake Clutch – Typical

E42715

ItemDescription

1	Input shaft
2	Main pressure supply port
3	Piston
4	Cylinder – External plate carrier
5	Clutch plate assembly
6	Baffle plate

7	Diaphragm spring
8	Output shaft
9	Bearing
10	Dynamic pressure equalisation chamber
11	Piston chamber
12	Lubrication channel

There are 3 drive clutches and 2 brake clutches used in the 6HP26 transmission. Each clutch comprises one or more friction plates dependent on the output controlled. A typical clutch consists of a number of steel outer plates and inner plates with friction material bonded to each face.

On supercharged models, the uprated transmission includes additional clutch plates to enable the transmission to manage the additional power output of the supercharged engine.

The clutch plates are held apart mechanically by a diaphragm spring and hydraulically by dynamic pressure. The pressure is derived from a lubrication channel which supplies fluid to the bearings etc. The fluid is passed via a drilling in the output shaft into the chamber between the baffle plate and the piston. To prevent inadvertent clutch application due to pressure build up produced by centrifugal force, the fluid in the dynamic pressure equalisation chamber overcomes any pressure in the piston chamber and holds the piston off the clutch plate assembly.

When clutch application is required, main pressure from the fluid pump is applied to the piston chamber from the supply port. This main pressure overcomes the low pressure fluid present in the dynamic pressure equalisation chamber. The piston moves, against the pressure applied by the diaphragm spring, and compresses the clutch plate assembly. When the main pressure falls, the diaphragm spring pushes the piston away from the clutch plate assembly, disengaging the clutch.

PLANETARY GEAR TRAINS

The planetary gear trains used on the 6HP26 transmission comprise a single web planetary gear train and a double web planetary gear train. These gear trains are known as Lepelletier type gear trains and together produce the 6 forward gears and the 1 reverse gear.

Single Web Planetary Gear Train

The single web planetary gear train comprises:

- 1 sunwheel
- 3 planetary gears
- 1 planetary gear carrier (spider)
- 1 ring gear or annulus

E42716

ItemDescription

1	Cylinder
2	Baffle plate
3	Ring gear

3	Ring gear
4	Output shaft
5	Planetary gear carrier
6	Sunwheel
7	Double planetary gears (long)
8	Sunwheel

The double planetary gear train comprises:

- 2 sunwheels
- 3 short planetary gears
- 3 long planetary gears
- 1 planetary gear carrier
- 1 ring gear or annulus

ELECTRONIC PARK LOCK

The park lock is electronically actuated by solenoid valve located in the valve block. The park lock is engaged by a mechanical spring system comprising a parking disc and a lock cylinder controlled by a solenoid valve.

The park lock is engaged when the [TCM](#) receives a park request from the JaguarDrive selector. When the park lock is released, a solenoid valve in the valve housing directs hydraulic pressure to the lock cylinder, which moves the piston within the cylinder and releases the park lock pawl at the rear of the transmission by means of a connecting rod. The solenoid on the lock cylinder is energized and locks the cylinder piston in the unlocked position. Additional locking of the piston is achieved with ball catches within the lock cylinder.

When park is selected, the solenoid on the lock cylinder is de-energized, the ball catches are released and the piston is free to move in the lock cylinder. The solenoid in the valve housing is also de-energized. The spring loaded parking disc pulls the cylinder piston in the park direction which allows the park disc to move on its mounting. This movement is transferred via the connecting rod to parking pawl, which is engaged in the park lock gear.

If an electrical failure occurs, the park lock can be manually released by means of an emergency park release lever located in the floor console. The lever is connected to the parking disc by a cable and allows the park lock to be released manually.

Description and Operation

OVERVIEW

The [TCM \(transmission control module\)](#) is an integral part of the Mechatronic valve block which is located at the bottom of the transmission, within the fluid pan. The [TCM](#) is the main controlling component of the transmission.

The [TCM](#) processes signals from the transmission speed and temperature sensors, [ECM \(engine control module\)](#) and other vehicle systems. From the received signal inputs and pre-programmed data, the module calculates the correct gear, torque converter clutch setting and optimum pressure settings for gear shift and lock-up clutch control.

Unlike previous transmissions, this application has a fully electronic, JaguarDrive selector with no Bowden cable connection to the transmission. The transmission selections are made using a rotary JaguarDrive selector which rises from the floor console once the engine is running. Rotation of the JaguarDrive selector to any of the 5 positions is sensed by the [TCM](#) which reacts according to the selected position.

Another new feature is the electronic park lock which is controlled by the [TCM](#). A mechanical link is fitted for emergency park release in the event of an electrical failure.

System Operation

TRANSMISSION CONTROL MODULE OPERATION

The [TCM](#) outputs signals to control the shift control solenoid valve and the Electronic Pressure Regulator Solenoids (EPRS) to control the hydraulic operation of the transmission.

The [TCM](#) processes signals from the transmission speed and temperature sensors, the [ECM](#) and other vehicle systems. From the received signal inputs and pre-programmed data, the module calculates the correct gear, torque converter clutch setting and optimum pressure settings for gear shift and lock-up clutch control.

The [ECM](#) supplies the engine management data over the high speed [CAN \(controller area network\)](#) bus. The [TCM](#) requires engine data to efficiently control the transmission operation, for example; flywheel torque, engine speed, accelerator pedal angle, engine temperature. The steering angle sensor and the [ABS \(anti-lock brake system\)](#) module also supply data to the [TCM](#) on the high speed [CAN](#) bus. The [TCM](#) uses data from these systems to suspend gear changes when the vehicle is cornering and/or the [ABS](#) module is controlling braking or traction control.

Using the signal inputs and the memorized data, the [TCM](#) control program computes the correct gear and torque converter lock-up clutch setting and the optimum pressure settings for gear shift and lock-up clutch control. Special output-side modules (power output stages, current regulator circuits), allow the [TCM](#) to control the solenoid valves and pressure regulators and consequently precisely control the hydraulics of the automatic transmission. In addition, the amount and duration of engine interventions are supplied to the engine management by way of the [CAN](#) bus.

The transmission has a fully electronic JaguarDrive selector with no Bowden cable connection to the transmission. The transmission selections are made using a rotary JaguarDrive selector which rises from the floor console once the engine is running. Rotation of the JaguarDrive selector to any of the 5 positions is sensed by the [TCM](#) via the high speed [CAN](#) bus. The [TCM](#) then reacts according to the selected position. The 'Sport' (S) position selection allows the [TCM](#) to operate the transmission using the semi-automatic 'Jaguar Sequential Shift'.

Gear selections are sensed by the [TCM](#) when the driver operates the steering wheel paddle switches. Once the JaguarDrive selector position is confirmed, the [TCM](#) outputs appropriate information on the high speed [CAN](#) bus.

If the JaguarDrive selector is in 'D', 'Jaguar Sequential Shift' is temporary and will cancel after a time period or can be cancelled by pressing and holding the + paddle for approximately 2 seconds.

If the JaguarDrive selector is in 'S', 'Jaguar Sequential Shift' is permanent and can only be cancelled by pressing and holding the + paddle for approximately 2 seconds or by moving the JaguarDrive selector to the 'D' position.

The [TCM](#) can be reprogrammed using an approved Jaguar diagnostic system using a flash code. The [TCM](#)'s processor has a 440 Kb internal flash memory. Of this capacity, approximately 370 Kb are used by the basic transmission program. The remainder, approximately 70 Kb is used to store vehicle-specific application data.

Engine Stall

If the vehicle stalls it will coast down in gear, with the transmission providing drive to the engine. A restart can be attempted at this point and the engine may start and the driver can continue.

If the coast down speed reduces such that the speed of the engine is less than 600rpm, the transmission will go to neutral, D illumination will flash in the instrument cluster. The driver needs to select neutral or park and then press the brake pedal to restart the engine.

If the driver presses the start/stop button when driving, there will be no change to the ignition state, the driver will receive a message in the instrument cluster "Start button Pressed". If the driver requires to switch off the engine, the start/stop button must be pressed for a second time. The engine will be stopped and will be back driven by the transmission as the vehicle coasts down. When the engine speed is less than 600 rpm the transmission engages neutral (flashing D illumination in the instrument cluster). When vehicle speed is less than 2 km/h (1.2 mph) Park is engaged. The JaguarDrive selector automatically rotates back to its lowered P position and the vehicle ignition is switched off.

The park engagement is prevented in a stall case as the ignition power is on and D was the last selected gear. The park engagement speed at ignition off is from the least value of the wheel speeds ([CAN](#) signal) and transmission output speed (internal signal).

Component Description

TRANSMISSION CONTROL MODULE DESCRIPTION

The [TCM](#) is an integral part of the Mechatronic valve block which is located at the bottom of the transmission, within the fluid pan. The [TCM](#) is the main controlling component of the transmission.

The Mechatronic valve block also contains the speed and temperature sensors. These are integral with the Mechatronic valve block and cannot be serviced individually. The speed sensors measure the transmission input and output speeds and pass signals to the [TCM](#). The fluid temperature sensor is also located in the valve block and measures the fluid temperature of the transmission fluid in the fluid pan.

Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Diagnostic Strategy

Diagnosis and Testing

Principle of Operation

For a detailed description of the automatic transmission/transaxle, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

[Transmission Electronic Control System - Vehicles With: ZF 6HP26](#) (Description and Operation),
[Transmission Electronic Control System - Vehicles With: ZF 6HP26](#) (Description and Operation),
[Transmission Electronic Control System - Vehicles With: ZF 6HP26](#) (Description and Operation).

Fluid Level and Condition Check

CAUTION: The vehicle should not be driven if the fluid level is low as internal failure can result.

• **NOTE:** The transmission fluid temperature must not be allowed to exceed 50°C (122°F) whilst checking level. Should the temperature rise above this figure, abort the check and allow the transmission fluid to cool to below 30°C (86°F).

This vehicle is not equipped with a fluid level indicator. An incorrect level may affect the transmission operation and could result in transmission damage. To correctly check and add fluid to the transmission.

REFER to: [Transmission Fluid Level Check](#) (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, General Procedures).

High Fluid Level

A fluid level that is too high may cause the fluid to become aerated due to the churning action of the rotating internal parts. This will cause erratic control pressure, foaming, loss of fluid from the vent tube and possible transmission damage. If an overfill condition is identified, with the engine at idle ensure the fluid temperature is within the specified range and allow the excess fluid to drain until a small thread of fluid runs from the filler/level plug hole.

Low Fluid Level

A low fluid level could result in poor transmission engagement, slipping, or damage. This could also indicate a leak in one of the transmission seals or gaskets.

REFER to: [Transmission Fluid Level Check](#) (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, General Procedures).

Adding Fluid

CAUTION: The use of any other type of transmission fluid other than that specified can result in transmission damage.

If fluid needs to be added, add fluid in 0.50 liter increments through the fill hole opening. Do not overfill the fluid. For fluid type, refer to the Specification section in this section.

REFER to: [Specifications](#) (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Specifications).

Fluid Condition Check

1. **1.** Check the fluid level.
REFER to: [Transmission Fluid Level Check](#) (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, General Procedures).
2. **2.** Observe the color and the odor of the fluid. The color under normal circumstances should be like honey, not dark brown or black.
3. **3.** Allow the fluid to drip onto a facial tissue and examine the stain.
4. **4.** If evidence of solid material is found, the transmission fluid pan should be removed for further inspection.

NOTE: In the event of a transmission unit replacement for internal failure, the oil cooler and pipes must also be replaced.

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. **1.** Verify the customer concern.
2. **2.** Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical	Hydraulic
<ul style="list-style-type: none"> ● Damaged/stuck shift mechanism ● Damaged automatic transmission casing 	<ul style="list-style-type: none"> ● Blown fuse(s) ● Damaged, loose or corroded connectors ● Wiring harness 	<ul style="list-style-type: none"> ● Fluid level too high/low ● Poor condition of fluid ● Fluid leak

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the cause is not visually evident check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

- NOTE: If the control module/transmission is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/transmission.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).
- NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: Inspect connectors for signs of water ingress, and pins for damage and/or corrosion.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B108782	Lost LIN Communications with ETS	<ul style="list-style-type: none"> ● Alivecounter fault 	Check transmission shift module for related DTCs and refer to the relevant DTC Index. Refer to the electrical circuit diagrams and check TCM to transmission shift module for short, open circuit

Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission Fluid Drain and Refill

General Procedures

Special Tool(s)	
	Adapter 307-452
307-452	

-  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

- Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
- Place a container under the transmission.

4. WARNINGS:

Observe due care when draining, as the fluid can be very hot.

Observe due care when working near a hot exhaust system.

Using the special tool, remove the transmission fluid filler/level plug.

5. WARNINGS:

Observe due care when draining, as the fluid can be very hot.

Observe due care when working near a hot exhaust system.

Remove the transmission fluid drain plug.

- Allow the fluid to drain.

6. Install the new transmission fluid drain plug.

- Tighten to 8 Nm.

7. NOTE: Use transmission fluid meeting Jaguar specification.

Refill the transmission with fluid.

8. Allow the transmission fluid to drain from the transmission fluid filler plug hole until the flow almost stops.

9. NOTE: Install a new sealing washer.

Using the special tool, install the new transmission fluid fill plug.

- Loosely install the transmission fluid fill plug.

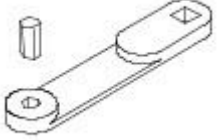

10. Lower the vehicle.

11. Carry out a transmission fluid level check.

For additional information, refer to: [Transmission Fluid Level Check](#) (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, General Procedures).

Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission Fluid Level Check

General Procedures

Special Tool(s)	
 <p>307-452</p>	Adapter 307-452

1. The following steps must be observed before starting the transmission fluid level check.

- The vehicle must be on a horizontal ramp.
- The parking brake must be applied.
- The engine must be running for 2 minutes with the transmission control switch (TCS) in the "P" position.

2. Connect the Jaguar approved diagnostic system.

3. Make sure that the TCS is in the "P" position.

4. **NOTE:** Make sure the transmission fluid temperature is below 30 °C (86 °F) on the Jaguar approved diagnostic system.

With the engine running and the foot brake applied, circulate the transmission fluid by:

- Moving the TCS to the "R" position.
- Waiting for 3 seconds.
- Moving the TCS to the "D" position.
- Waiting for 3 seconds.
- Moving the TCS to the "P" position.

5.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

6. Remove the air deflector.

For additional information, refer to: Air Deflector (501-02, Removal and Installation).

7. Place a suitable container under the transmission fluid fill plug.

8.  **WARNING:** Make sure that care is exercised near rotating parts. Failure to follow this instruction may result in personal injury.

With the engine running, using the special tool remove the transmission fluid fill plug.

- Remove and discard the transmission fluid fill plug.

9. **NOTE:** Use transmission fluid meeting Jaguar specification.

If the transmission fluid does not come out of the transmission fluid fill plug hole the transmission fluid level is insufficient. If this is the case add the transmission fluid in 0.5 liter units into the transmission fluid fill plug hole until fluid comes out.

10. **NOTE:** Make sure the transmission fluid temperature does not exceed 50 °C (122 °F). If the transmission fluid temperature does exceed 50 °C (122 °F) stop the transmission fluid level check and allow the transmission fluid to cool until the temperature is below 30 °C (86 °F).

Allow the transmission fluid to drain from the transmission fluid filler plug hole until the flow almost stops.

11. NOTE: Install a new sealing washer.

Using the special tool, install the new transmission fluid fill plug.

12. ⚠ CAUTION: Make sure the transmission fluid fill plug is tightened to the correct specification. Failure to follow this instruction may result in damage to the vehicle.

Using the special tool and torque wrench, tighten the transmission fluid fill plug.

E37107

- To make sure the transmission fill plug is torqued to the correct specification. Using the special tool and torque wrench the following calculation steps must be followed.
- Step 1. Multiply 35 Nm by the effective length of the torque wrench (1).
- Step 2. Add the effective length of the special tool (2) to the effective length of the torque wrench (1).
- Step 3. Divide the total of step 1 by the total of step 2.
- Step 4. Set the torque wrench to the figure arrived at in step 3.
- Tighten the transmission fluid fill plug to the torque given by the calculation.

13. Remove the special tool.

14. Remove the container.

15. Install the air deflector.

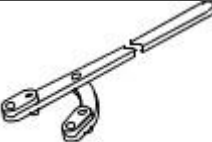

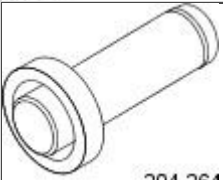

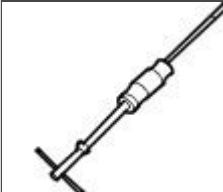

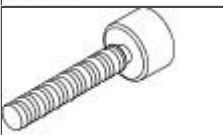

For additional information, refer to: Air Deflector (501-02, Removal and Installation).

16. Lower the vehicle.

17. Disconnect the Jaguar approved diagnostic system.

Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Extension Housing Seal

 E52696	Socket Output Flange Remover/Installer 205-789

Removal

1. CAUTIONS:

 Under no circumstances must the flexible coupling (or its fixings) be loosened or removed from the driveshaft. Failure to follow this instruction may result in damage to the vehicle.

 Make sure the front of the driveshaft does not put an excessive load on the center bearing. Failure to follow this instruction may result in damage to the vehicle.

Detach the driveshaft from the transmission flange.

- Mark the position of the driveshaft in relation to the transmission flange.
- Mark the position of each nut and bolt in relation to the transmission flexible joint.

2. Loosen the heat shield retaining nut.

3. Install suitable cord to the heat shield retaining nut stud.

- Tighten the retaining nut.

4. Reposition the driveshaft.

5. Using the special tool, remove the transmission support.

- Lower the transmission to a suitable height.

6. Using the special tools, remove and discard the output shaft flange retaining nut.

7. Using the special tool, remove the output shaft flange.

- Remove the output shaft flange spacing shim.

8. **⚠ CAUTION:** Make sure the transmission housing seal face is not damaged when removing the extension housing seal. Failure to follow this instruction may result in damage to the vehicle.

Using the special tools, remove the extension housing seal.

9. NOTE: Using a suitable metal surface cleaner meeting Jaguar specification, clean the seal face on the housing before installing the new seal.

Clean and inspect the transmission housing seal face.

Installation

1. Using the special tool, install the extension housing seal.

2. Using the special tools install a new output shaft flange retaining nut.

- Install the output shaft flange spacing shim.
- Install the output shaft flange.
- Tighten to 60 Nm.

3. Install the transmission support.

- Using the special tool, raise the transmission.
- Tighten to 55 Nm.

4. Tighten to 48 Nm.

5.  CAUTION: Make sure the front of the driveshaft does not put an excessive load on the center bearing. Failure to follow this instruction may result in damage to the vehicle.

Reposition the driveshaft.

- Undo the cord.

6. Loosen the retaining nut.

- Remove the cord from the heat shield retaining nut stud.

7. Tighten the retaining nut.

8. CAUTIONS:

 Make sure the front of the driveshaft does not put an excessive load on the center bearing. Failure to follow this instruction may result in damage to the vehicle.

 Make sure all components are installed to the position they were removed from. Failure to follow this instruction may result in damage to the vehicle.

Attach the driveshaft to the transmission flange.

- Tighten to 88 Nm.

9. Carry out a transmission fluid level check.
For additional information, refer to: Transmission Fluid Level Check (307-01, General Procedures).

Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission Fluid Pan, Gasket and Filter

In-vehicle Repair

Removal

All vehicles

1. Disconnect the battery ground cable.
For additional information, refer to: Battery Disconnect (414-01, General Procedures).

Vehicles with diesel engine

2. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).

All vehicles

3. Drain the transmission.
For additional information, refer to: Transmission Fluid Drain and Refill (307-01, General Procedures).

Vehicles with diesel engine

4. Detach the catalytic converter temperature sensor wiring harness from the fluid pan.

E67133

All vehicles

5. **NOTE:** Discard the fluid pan, gasket and filter.

Remove the fluid pan, gasket and filter.

- Remove the retaining bolts.

E30825

Installation

All vehicles

1. Install the new fluid pan, gasket and filter.

- Tighten to 8 Nm.

Vehicles with diesel engine

2. Attach the catalytic converter temperature sensor wiring harness onto the fluid pan.

All vehicles

3. Fill the transmission.

For additional information, refer to: Transmission Fluid Drain and Refill (307-01, General Procedures).

Vehicles with diesel engine

4. Install the air deflector.

For additional information, refer to: Air Deflector (501-02, Removal and Installation).

All vehicles

5. Lower the vehicle.

6. Connect the battery ground cable.

For additional information, refer to: Battery Connect (414-01, General Procedures).

Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission Control Module (TCM) and Main Control Valve Body

In-vehicle Repair

General Equipment

Anti-Static Wrist Strap

Removal

1. Remove the fluid pan, gasket and filter.
For additional information, refer to: [Transmission Fluid Pan, Gasket and Filter](#) (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, In-vehicle Repair).

E30826

2.  **CAUTION:** Make sure the transmission control module (TCM) and main control valve body are protected against electrostatic discharge. Failure to follow this instruction may result in component damage.

Reposition the locking device.

3. Disconnect the TCM and main control valve body electrical connector.

1. Reposition the electrical connector retaining ring.
2. Disconnect the electrical connector.

E30827

4.  **CAUTION:** Make sure all suitable safety precautions are taken to protect the TCM and main control valve body electrical connector pins against electrostatic discharge.

Remove the sealing tube.

E30828

5. Remove and discard the seals.

E30831

6. Remove the TCM and main control valve body.

- Remove the retaining bolts.

E30829

7. Remove the TCM and main control valve body sealing block.

E31203

8. Remove and discard the seals.

E30830

9. Remove and discard the seals.

Installation

1. Install the new seals.

2. Install the new seals.

3. Install the TCM and main control valve body sealing block.

E30833

4.  CAUTION: Make sure the TCM and main control valve body are protected against electrostatic discharge. Failure to follow this instruction may result in component damage.

Align the transmission selector shaft to the TCM and main control valve body.

E30829

5. Install the TCM and main control valve body retaining bolts.

- Tighten to 8 Nm.

E30831

6. Install the new seals.

E30828

7.  CAUTION: Make sure all suitable safety precautions are taken to protect the TCM and main control valve body electrical connector pins against electrostatic discharge.

Install the sealing tube.

8. Reposition the TCM and main control valve body electrical connector retaining ring.

1. Connect the electrical connector.
2. Reposition the electrical connector retaining ring.

9. Reposition the locking device.

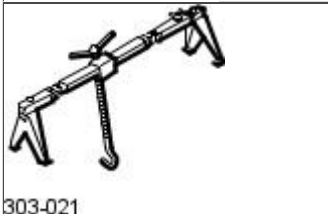

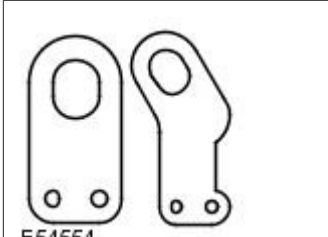

10. Install the fluid pan, gasket and filter.

For additional information, refer to: [Transmission Fluid Pan, Gasket and Filter](#) (307-01 Automatic Transmission/Transaxle - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, In-vehicle Repair).

Removal

1. Place the transmission control switch (TCS) knob in the N position.
2. Release the electronic parking brake.
3. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
4. Remove the engine cover.
For additional information, refer to: [Engine Cover - TDV6 2.7L Diesel](#) (501-05 Interior Trim and Ornamentation, Removal and Installation).
5. Install the special tool.

6. Install the special tool.

- Rotate the special tool adjustment bolt a suitable amount of turns to support the engine.

7.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

8. Remove the catalytic converters.

For additional information, refer to: [Catalytic Converter](#) (309-00A Exhaust System - TDV6 2.7L Diesel, Removal and Installation).

9. NOTE: Some variation in the illustrations may occur, but the essential information is always correct.

Release and disconnect the 2 transmission wiring harness electrical connectors.

E 30850

VUJ0004977

10.  CAUTION: Under no circumstances must the flexible coupling (or it's fixings) be loosened or removed from the driveshaft.

• NOTE: Note the fitted position of the component/s prior to removal.

Detach the driveshaft from the transmission flange.

- Mark the position of the driveshaft in relation to the transmission flange.
- Mark the position of each nut and bolt in relation to the transmission flexible joint.
- Tie aside.

E51535

11. Release the transmission fluid cooler tubes.

- Allow the transmission fluid to drain into a suitable container.
- Remove and discard the O-ring seals.
- Install blanking caps to the exposed ports.

E52091

12. Detach the transmission fluid cooler tubes from the retaining bracket.

13. Detach the transmission park interlock release cable from the transmission.

- Release the transmission park interlock release cable from the transmission park interlock release lever.

14. Detach the diesel particulate filter (DPF) high and low-pressure pipes from the transmission.

15. Remove the right-hand turbocharger outlet pipe.

- Remove the bolt.
- Release the turbocharger outlet pipe clip.
- Detach the wiring harness clip.

16. NOTE: Some variation in the illustrations may occur, but the essential information is always correct.

Remove the rubber access cover.

E51614

17. NOTE: Some variation in the illustrations may occur, but the essential information is always correct.

Remove the 4 retaining bolts.

- Rotate the torque converter to align with the flexplate bolt holes.

E51615

18. Install the special tool.

19. Using the special tool, lower the rear of the transmission.

- Remove the retaining bolts.

20.  **WARNING:** Secure the transmission to the transmission jack.
Secure the retaining strap.

21. Remove the retaining bolts.

22. Remove the retaining bolts.

23. Remove the retaining bolts.

24. Remove the transmission and converter.

1. Remove the retaining bolts.
2. Displace the transmission from the engine locating dowels.
3. Lower the transmission.

25. With assistance, remove the transmission from the special tool.

26. **NOTE:** Do not disassemble further if the component is removed for access only.

Remove the wiring harness.

- Disconnect the electrical connector.
- Release the 3 wiring harness clips.

27. Remove the transmission rear support bracket.

- Remove the two support bracket retaining bolts.

Removal

1. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

2.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

3. Remove the air deflector.
For additional information, refer to: [Air Deflector](#) (501-02 Front End Body Panels, Removal and Installation).
4. Remove the engine rear undershield.
For additional information, refer to: [Engine Rear Undershield](#) (501-02 Front End Body Panels, Removal and Installation).
5. Remove the catalytic converters.
For additional information, refer to: [Catalytic Converter](#) (309-00B Exhaust System - V6 3.0L Petrol, Removal and Installation).
6. Remove the starter motor.
For additional information, refer to: [Starter Motor](#) (303-06B Starting System - V6 3.0L Petrol, Removal and Installation).

7.  **CAUTION:** Under no circumstances must the flexible coupling (or it's fixings) be loosened or removed from the driveshaft.

- **NOTE:** Note the fitted position of the component/s prior to removal.

Detach the driveshaft from the transmission flange.

- Mark the position of the driveshaft in relation to the transmission flange.
- Mark the position of each nut and bolt in relation to the transmission flexible joint.

8.  **CAUTION:** Always plug any open connections to prevent contamination.

- **NOTE:** Position cloth to collect fluid spillage.

Release the transmission fluid lines.

- Remove the bolt.
- Remove and discard both O-ring seals.

9. Detach the transmission park interlock release cable from the transmission.

- Release the transmission park interlock release cable from the transmission park interlock release lever.

10. Release the torque converter from the flexplate.

- Remove the access plugs.
- Rotate the crankshaft to access the retaining bolts.
- Remove the 3 bolts.

11. Using a transmission jack, support the transmission.

12. Release the transmission support insulator.

- Remove the 4 bolts.

13. Release the wiring harness from the RH side of the transmission.

- Disconnect the transmission electrical connector.
- Carefully release the 3 clips.

14. Install the torque converter retainer.

15. WARNINGS:

Secure the transmission to the transmission jack.

Support the engine. The engine will fall forward when the transmission is removed.

CAUTION: Make sure the torque converter remains connected to the transmission.

With assistance, remove the transmission.

- Remove the 15 bolts.

Installation

-  **CAUTION:** If installing a new transmission, the oil cooler must be flushed.

Flush the transmission oil cooler and fluid tubes.

- Install the transmission rear support bracket.
 - Install the the two support bracket retaining bolts.
 - Tighten to 45 Nm.

- Attach the wiring harness.
 - Attach the 3 wiring harness clips.
 - Connect the electrical connector.

4. With assistance, install the transmission to the special tool.

- Secure the retaining strap.

5.  **CAUTION:** Apply grease of the correct specification to the torque converter spigot.

Apply a thin layer of high-temperature grease to the centering spigot bore on the torque converter.

6.  **CAUTION:** Make sure the torque converter remains connected to the transmission.

Install the transmission and converter.

- Using a transmission jack, carefully raise the assembly.
- Make sure the transmission engages correctly with the engine locating dowels.
- Loosely install the bolts.

7. Install the retaining bolts.

- Tighten to 48 Nm.

8. Install the retaining bolts.

- Tighten to 48 Nm.

9. Install the retaining bolts.

- Tighten to 48 Nm.

10. Install the retaining bolts.

- Tighten to 48 Nm.

11. Tighten to 48 Nm.

12. Remove the retaining strap.

13. Using the special tool, raise the rear of the transmission.

- Install the retaining bolts.
- Tighten to 50 Nm.

14. Remove the special tool.

15. NOTE: Some variation in the illustrations may occur, but the essential information is always correct.

Install the retaining bolts.

- Rotate the torque converter to align with the flexplate bolt holes.
- Tighten to 55 Nm.

E51615

16. NOTE: Some variation in the illustrations may occur, but the essential information is always correct.

Install the rubber access cover.

E51614

17. Install the right-hand turbocharger outlet pipe.

- Secure the turbocharger outlet pipe clip.
- Install and tighten the bolt.
- Tighten to 9 Nm.
- Attach the wiring harness clip.

E98850

18. Attach the DPF high and low-pressure pipes to the transmission.

- Tighten to 9 Nm.

19. Attach the transmission park interlock release cable to the transmission.

- Secure the transmission park interlock release cable to the transmission park interlock release lever.
- Tighten to 9 Nm.

20. Attach the transmission fluid cooler tubes to the automatic transmission.

- Install new O-ring seals.
- Lubricate the O-ring seals.
- Tighten to 23 Nm.

21. Attach the transmission fluid cooler tubes to the retaining bracket.

22. NOTE: Install the components to their original fitted positions.

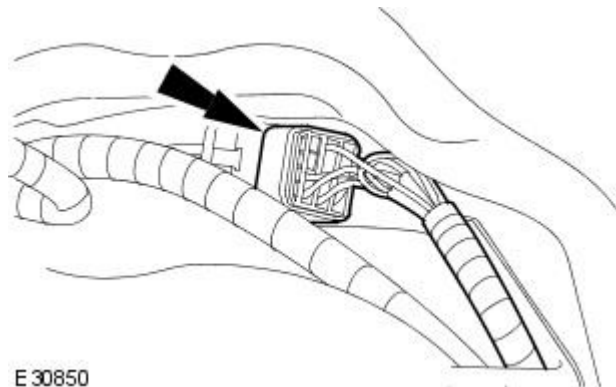

Attach the driveshaft to the transmission flange.

- Tighten to 127 Nm.

23. NOTE: Some variation in the illustrations may occur, but the essential information is always correct.

Connect the transmission wiring harness electrical connectors.

24. Install the catalytic converters.

For additional information, refer to: [Catalytic Converter](#) (309-00A Exhaust System - TDV6 2.7L Diesel, Removal and Installation).

25. Lower the vehicle.

26. Remove the special tool.

27. Install the engine cover.

For additional information, refer to: [Secondary Bulkhead Center Panel](#) (501-02 Front End Body Panels, Removal and Installation).

28. Connect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

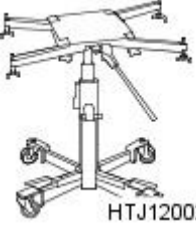

29. Apply the electronic parking brake.

30. Check and top-up the transmission fluid level.

For additional information, refer to: [Transmission Fluid Level Check](#) (307-01 Automatic Transmission/Transaxle - V8 4.2L Petrol/V8 S/C 4.2L Petrol/V6 3.0L Petrol/TDV6 2.7L Diesel, General Procedures).

Transmission/Transaxle Cooling - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission Cooling Vehicles With: ZF 6HP26 - Overview

Description and Operation

OVERVIEW

All models have transmission fluid coolers.

On models with petrol engines, the fluid cooler is incorporated into the [LH \(left-hand\)](#) end tank of the engine cooling radiator.

On models with diesel engines, the fluid cooler is a dedicated cooler unit located near the lower front [LH](#) side of the engine compartment.

Transmission/Transaxle Cooling - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission Cooling Vehicles With: ZF 6HP26 - System Operation and Component Description

Description and Operation

System Operation

MODELS WITH V8 AND V6 PETROL ENGINES

Fluid is supplied from the transmission fluid pump into the upper connection of the engine cooling radiator. After passing through the radiator in tank cooler, the fluid passes out of the lower connection and is returned to the transmission fluid pan.

MODELS WITH 2.7L V6 DIESEL ENGINE

Fluid is supplied from the transmission fluid pump into the forward most connection of the cooler. After passing through the cooler, the fluid passes out of the rearmost connection and is returned to the transmission fluid pan.

Component Description

MODELS WITH V8 AND V6 PETROL ENGINES

The transmission fluid cooler is integrated into the [LH \(left-hand\)](#) end tank of the engine cooling radiator. The transmission fluid is cooled by the temperature differential between the transmission fluid and the engine coolant.

The fluid cooler is an aluminium cooler comprising louvered fins and plates. The plates allow a cross-flow of transmission fluid through the cooler. The fins are immersed in engine coolant on the 'cold' side of the radiator which provides cooling of the transmission fluid via heat transfer.

This fluid cooler design provides an advantage over an air-cooled cooler in that the fluid cooling is controlled with engine coolant temperature. Fluid temperature control is also improved when the vehicle is moving slowly or is stationary with the engine running.

MODELS WITH 2.7L V6 DIESEL ENGINE

The transmission fluid cooler is a separate cooling unit located behind the engine cooling radiator. The transmission is connected to the fluid cooler via flexible hoses and metal pipes.

The transmission fluid cooler is a dedicated fluid cooler which is connected into the engine cooling system circuit. The transmission fluid is cooled by the temperature differential between the transmission fluid and the engine coolant flowing through the cooler.

Transmission/Transaxle Cooling - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Transmission Cooling

Diagnosis and Testing

Principle of Operation

For a detailed description of the automatic transmission cooling system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (307-02 Transmission/Transaxle Cooling - 2.7L V6 - TdV6/3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

[Transmission Cooling - Vehicles With: ZF 6HP26](#) (Description and Operation),
[Transmission Cooling - Vehicles With: ZF 6HP26](#) (Description and Operation),
[Transmission Cooling - Vehicles With: ZF 6HP26](#) (Description and Operation).

Inspection and Verification

1. 1. Verify the customer concern by operating the system.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical
<ul style="list-style-type: none"> ● Feed and return tubes ● Connections to the automatic transmission and the automatic transmission fluid cooler ● Automatic transmission fluid level

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the concern is not visually evident, verify the symptom and refer to the Symptom Chart.

Symptom Chart

Condition	Possible Cause	Action
Over heating of the automatic transmission	Obstruction in the automatic transmission fluid cooler	Flush out the automatic transmission fluid cooler with new automatic transmission fluid. If the flushing is unsuccessful, install a new transmission fluid cooler. REFER to: Transmission Fluid Cooler (307-02, Removal and Installation).
Over heating of the automatic transmission	Obstruction in the automatic transmission fluid tubes	Flush out the automatic transmission fluid cooler tubes with new automatic transmission fluid. If the flushing is unsuccessful install new automatic transmission fluid cooler tubes. REFER to: Transmission Fluid Cooler Tubes (307-02, Removal and Installation).
Loss of automatic transmission fluid	Connections to the automatic transmission and the automatic transmission fluid cooler	Check the integrity of the tubes, connections and seals. Check the torque of the tube fixings. REFER to: Specifications (307-02, Specifications).
Loss of automatic transmission fluid	Leak at oil cooler	Check the integrity of tubes, connections and seals. Check the torque of the tube fixings. REFER to: Specifications (307-02, Specifications).

Automatic Transmission/Transaxle External Controls - External Controls Vehicles With: ZF 6HP26 - Overview

Description and Operation

OVERVIEW

The [TCM \(transmission control module\)](#) contains software to provide operation as a semi-automatic 'Jaguar Sequential Shift' transmission.

The [TCM](#) allows the transmission to be operated as a conventional automatic unit by selecting P, R, N, D on the JaguarDrive selector. Unlike previous transmissions, this application uses a fully electronic rotary transmission selector with no mechanical connection to the transmission.

Rotation of the JaguarDrive selector allows the selection of Park (P), Reverse (R), Neutral (N) and Drive (D). By depressing the JaguarDrive selector and rotating clockwise from the 'D' position, Sport (S) mode can be selected.

Two gear change 'paddle' switches are fitted at the rear of the steering wheel and allow the driver to operate the transmission as a semi-automatic manual gearbox using the Jaguar Sequential Shift feature.

Four additional switches are located adjacent to the JaguarDrive selector and control the JaguarDrive Optimisation Control functions.

Refer to: [Anti-Lock Control - Stability Assist](#) (206-09 Anti-Lock Control - Stability Assist, Description and Operation).

7	Steering wheel audio switch assembly
8	Upshift paddle switch
9	Downshift paddle switch
10	Instrument cluster

System Operation

JAGUARDRIVE SELECTOR

Rotation of the JaguarDrive selector to any of the 5 positions is sensed by the [TCM](#) via the high speed [CAN \(controller area network\)](#) bus. A [LIN \(local interconnect network\)](#) bus connection is also provided but is only used in the event of a [CAN](#) bus failure as a back-up. The [TCM](#) then reacts according to the selected position. The JaguarDrive selector is a magnetic system using Hall effect sensors to determine the selected position of the selector.

The 'Sport' (S) position selection allows the [TCM](#) to operate the transmission using the semi-automatic 'Jaguar Sequential Shift'. Gear selections are sensed by the [TCM](#) when the driver operates the steering wheel paddle switches. Once the JaguarDrive selector position is confirmed, the [TCM](#) outputs appropriate information on the high speed [CAN](#) bus which is received by the instrument cluster to display the gear selection information in the message center. Refer to: [Information and Message Center](#) (413-08 Information and Message Center, Description and Operation) / [Information and Message Center](#) (413-08, Description and Operation).

The paddles can also be used on a temporary basis when the JaguarDrive selector is in the 'D' position to override the automatic gear selection if required.

PADDLE SWITCHES

Each paddle switch has 3 connections; ground, illumination ([PWM \(pulse width modulation\)](#)) supply and ground switch signal. The paddle switches are hardwired to the steering wheel audio switches. Operation of the paddle switch completes a ground path to the audio switch assembly. The audio switch assembly converts the completed ground signal into a [LIN](#) bus signal which is passed via the clockspring to the instrument cluster. The instrument cluster converts the signal into a high speed [CAN](#) bus signal to the [TCM](#).

Pulling the [LH \(left-hand\)](#) downshift - paddle provides down changes and pulling the [RH \(right-hand\)](#) upshift (+) paddle provides up changes. The first operation of either paddle, after Sport mode is selected, puts the transmission into permanent manual 'Jaguar Sequential Shift' mode. Rotation of the JaguarDrive selector back to the 'D' position, returns the transmission to conventional automatic operation.

Temporary operation of manual 'Jaguar Sequential Shift' mode can also be operated with the JaguarDrive selector in the 'D' position. Operation of either the upshift or downshift paddles activates the manual mode operation. If the JaguarDrive selector is in 'D', 'Jaguar Sequential Shift' will cancel after a time period or can be cancelled by pressing and holding the + paddle for approximately 2 seconds.

Component Description

JAGUARDRIVE SELECTOR

E94657

ItemDescription

1	Emergency park release lever locking mechanism
2	Emergency park release lever
3	Trim cover - emergency park release lever
4	Parking brake switch
5	Dynamic mode switch
6	Automatic speed limiter switch
7	Slip control mode switch
8	Dynamic Stability Control (DSC) switch
9	JaguarDrive selector
10	Selector position LED (light emitting diode)
11	Start/Stop switch
12	Screw (5 off)
13	Release cable connector
14	Emergency park release lever cable

The JaguarDrive selector assembly is located in a central position in the floor console. The assembly is attached to a molding in the floor console with 5 screws.

Transmission selections are made using the rotary JaguarDrive selector which rises from the floor console once the engine is running. When the engine is stopped with the selector in any position other than 'N', the JaguarDrive selector retracts into the floor console. If the selector remains in position 'N' when the engine is stopped, the selector will remain in the

raised position for up to 10 minutes, for use in a drive through car wash for example. After 10 minutes the selector will automatically retract into the floor console or if 'P' is selected before the 10 minute period the selector will retract.

If JaguarDrive selector does not rise from the console when the engine is started but electrical power is supplied to the selector, selections can still be made by rotating the selector to the required position using your fingertip. If electrical power to the JaguarDrive selector is lost, the selector will not rise from the console when the engine is started and selections cannot be made by rotating the selector using your fingertip.

The JaguarDrive selector contains an internal interlock solenoid to prevent the selector from being rotated when the engine is not running.

The engine can be stopped with the JaguarDrive selector in any position. Once the engine is stopped the selector will automatically reset to the Park (P) position and the transmission park lock will be engaged, except if the selector is moved to the 'N' position when the engine is stopped.

Emergency Park Release

In the event of the vehicle requiring recovery, Park can be released manually with the use of the Emergency Park Release cable. To de-select Park, remove the trim cover from the rear of the floor console and locate the emergency park release lever. Rotate the locking mechanism of the release lever through 90 degrees in a counterclockwise direction to unlock the lever. Apply the footbrake and pull the lever upwards and ensure it is locked in the vertical position. This mechanically disengages the parking pawl and engages the transmission in neutral via a cable to the transmission.

When the Emergency Park Release lever is pulled, the vehicle will be able to free wheel.

To re-engage the transmission into Park, hold the strap on the emergency park release hand lever; release the latch and lower the hand lever to its horizontal position. Lock the hand lever by turning the locking mechanism 90 degrees in a clockwise direction and replace trim cover.

PARK INTERLOCK AND NEUTRAL LOCK

Neutral lock is a new feature introduced as a requirement for the JaguarDrive selector. The selector is always locked at ignition on when the engine is not running, except after an engine stall when the selector is not in 'P' or 'N'.

If, when driving with the JaguarDrive selector in 'S', 'D' or 'R' at a speed of more than 5 km/h (3 mph), the driver selects 'P' or 'N':

- without the brake pedal pressed, the JaguarDrive selector will be immediately locked once the vehicle speed falls to below 5 km/h (3 mph)
- with the brake pedal pressed, the JaguarDrive selector will remain locked for as long as the brake pedal remains pressed, regardless of vehicle speed.

The transmission will only engage Park once the vehicle speed is less than 2 km/h (1 mph).

If the driver selects 'N' and releases the brake pedal with a vehicle speed of less than 5 km/h (3 mph), the JaguarDrive selector will be locked 2 seconds after 'N' is selected. The selector will remain locked until the driver presses the brake pedal again.

To ensure that a driver request to change from a non-driving range ('N' for example) to a driving range ('D' for example), the park interlock and neutral lock features are used in conjunction with the 'intermediate position'.

If the transmission receives a range change request without the brake pedal pressed, the [TCM](#) initiates a 'soft lock' function. The transmission will remain in Park or Neutral, depending on the starting position.

If a transmission position letter is flashing in the message center and the vehicle has no drive, the driver must:

- press the brake pedal
- reselect 'N' or 'P' on the JaguarDrive selector
- then select the required driving range, ensuring that the brake pedal is pressed.

Rocking Function

The rocking function is a new feature introduced to compliment the neutral lock function. For all changes from a non-driving range to a driving range, it is necessary to press the brake pedal (to release either the Park interlock or Neutral lock).

In situations where the driver will require to change the gear selection from 'R' to 'D' or from 'D' to 'R' without brake pedal input (car park manoeuvring, 3 point turns or 'rocking' the vehicle from a slippery surface for example) the 'rocking function' gives a 2 second lock delay when 'N' is selected on the JaguarDrive selector and the brake pedal is not pressed.

Intermediate Position

If the JaguarDrive selector is rotated slowly from 'P' to 'S' and back to position 'P' with the brake pedal pressed, the 'R' or 'D' position display letter in the message center will flash and the transmission will remain in Park or Neutral depending on the previous starting position of the selector.

If the brake pedal is released when 'R' or 'D' is flashing in the message center and the JaguarDrive selector is rotated to the 'R' or 'D' position, the driver's required range will not be selected and the transmission will remain in Park or Neutral, depending on the previous starting position. This feature is known as 'soft lock'.

If the driving range letter in the message center is flashing and the vehicle has no drive, the driver should depress the brake pedal to reselect 'N' or 'P', and then select the required driving range ensuring the brake pedal is pressed.

Automatic Transmission/Transaxle External Controls - External Controls

Diagnosis and Testing

Principles of Operation

For a detailed description of the transmission external controls, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (307-05 Automatic Transmission/Transaxle External Controls)

[External Controls - Vehicles With: ZF 6HP26](#) (Description and Operation),
[External Controls - Vehicles With: ZF 6HP26](#) (Description and Operation),
[External Controls - Vehicles With: ZF 6HP26](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Check for stuck/jammed switches and buttons ● Visibly damaged or worn components ● Loose or missing fasteners 	<ul style="list-style-type: none"> ● Fuse(s) ● Loose or corroded electrical connector(s)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

- NOTE: If the control module/component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).
- NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: Inspect connectors for signs of water ingress, and pins for damage and/or corrosion.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Exhaust System - TDV6 2.7L Diesel - Exhaust System - Overview

Description and Operation

OVERVIEW

The 2.7L V6 diesel exhaust system is fabricated from stainless steel and is supplied as 6 separate assemblies; a front section incorporating a catalytic converter for each bank of cylinders and the Diesel Particulate Filter (DPF) and a rear section incorporating a center silencer and two rear silencers.

The system is attached to the underside of the body with mounting rubbers which are located on mild steel hanger bars that are welded to the system. The mounting rubbers locate on corresponding hangers which are welded or bolted to the underside of the vehicle body.

The exhaust system incorporates a DPF which allows the vehicle to exceed European Stage 4 emission standards.

Exhaust System - TDV6 2.7L Diesel - Exhaust System - System Operation and Component Description

Description and Operation

System Operation

DIESEL PARTICULATE FILTER (DPF)

Passive Regeneration

Passive regeneration requires no special engine management intervention and occurs during normal engine operation. The passive regeneration involves a slow conversion of the particulate matter deposited in the DPF into carbon dioxide. This process is active when the DPF temperature reaches 250°C (482°F) and is a continuous process when the vehicle is being driven at higher engine loads and speeds.

During passive regeneration, only a portion of the particulate matter is converted into carbon dioxide. This is due to the chemical reaction process which is only effective within the normal operating temperature range of 250°C to 500°C (482°F to 932°F).

Above this temperature range the conversion efficiency of the particulates into carbon dioxide increases as the DPF temperature is raised. These temperatures can only be achieved using the active regeneration process.

Active Regeneration

Active regeneration starts when the particulate loading of the DPF reaches a threshold as monitored or determined by the DPF control software. The threshold calculation is based on driving style, distance travelled and back pressure signals from the differential pressure sensor.

Active regeneration generally occurs every 450 miles (725 km) although this is highly dependant on how the vehicle is driven. For example, if the vehicle is driven at low loads in urban traffic regularly, active regeneration will occur more often. This is due to the rapid build-up of particulates in the DPF than if the vehicle is driven at high speeds when passive regeneration will have occurred.

The DPF software incorporates a mileage trigger which is used as back-up for active regeneration. If active regeneration has not been initiated by a back pressure signal from the differential pressure sensor, regeneration is requested based on distance travelled.

Active regeneration of the DPF is commenced when the temperature of the DPF is increased to the combustion temperature of the particles. The DPF temperature is raised by increasing the exhaust gas temperature. This is achieved by introducing post-injection of fuel after the pilot and main fuel injections have occurred.

This is determined by the DPF software monitoring the signals from the two DPF temperature sensors to establish the temperature of the DPF. Depending on the DPF temperature, the DPF software requests the ECM to perform either one or two post-injections of fuel:

- The first post-injection of fuel retards combustion inside the cylinder which increases the temperature of the exhaust gas
- The second post-injection of fuel is injected late in the power stroke cycle. The fuel partly combusts in the cylinder, but some unburnt fuel also passes into the exhaust where it creates an exothermic event within the catalytic converter, further increasing the temperature of the DPF.

The active regeneration process takes approximately 20 minutes to complete. The first phase increases the DPF temperature to 500°C (932°F). The second phase further increases the DPF temperature to 600°C (1112°F) which is the optimum temperature for particle combustion. This temperature is then maintained for 15-20 minutes to ensure complete incineration of the particles within the DPF. The incineration process converts the carbon particles to carbon dioxide and water.

The active regeneration temperature of the DPF is closely monitored by the DPF software to maintain a target temperature of 600°C (1112°F) at the DPF inlet. The temperature control ensures that the temperatures do not exceed the operational limits of the turbocharger and the catalytic converter. The turbocharger inlet temperature must not exceed 830°C (1526°F) and the catalytic converter brick temperature must not exceed 800°C (1472°F) and the exit temperature must remain below 750°C (1382°F).

During the active regeneration process the following ECM controlled events occur:

- The turbocharger is maintained in the fully open position. This minimizes heat transmission from the exhaust gas to the turbocharger and reduces the rate of exhaust gas flow allowing optimum heating of the DPF. If the driver demands an increase in engine torque, the turbocharger will respond by closing the vanes as necessary
- The throttle is closed as this assists in increasing the exhaust gas temperature and reduces the rate of exhaust gas flow which has the effect of reducing the time for the DPF to reach the optimum temperature
- The Exhaust Gas Recirculation (EGR) valve is closed. The use of EGR decreases the exhaust gas temperature and therefore prevents the optimum DPF temperature being achieved.

If, due to vehicle usage and/or driving style, the active regeneration process cannot take place or is unable to regenerate the DPF, the dealer can force regenerate the DPF. This is achieved by either driving the vehicle until the engine is at its normal operating temperature and then driving for a further 20 minutes at speeds of not less than 30 mph (48 km/h) or by connecting a Jaguar approved diagnostic system to the vehicle which will guide the technician through an automated regeneration procedure to clean the DPF.

Diesel Particulate Filter Control

The DPF requires constant monitoring to ensure that it is operating at its optimum efficiency and does not become blocked. The ECM contains DPF software which controls the monitoring and operation of the DPF system and also monitors other vehicle data to determine regeneration periods and service intervals.

The DPF software can be divided into three separate control software modules; a DPF supervisor module, a DPF fuel management module and a DPF air management module.

These three modules are controlled by a fourth software module known as the DPF co-ordinator module. The co-ordinator module manages the operation of the other modules when an active regeneration is requested. The DPF supervisor module is a sub-system of the DPF co-ordinator module.

DPF Fuel Management Module

The DPF fuel management module controls the following functions:

- Timing and quantity of the four split injections per stroke (pilot, main and two post injections)
- Injection pressure and the transition between the three different calibration levels of injection.

The above functions are dependant on the condition of the catalytic converter and the DPF.

The controlled injection determines the required injection level in addition to measuring the activity of the catalytic converter and the DPF. The fuel management calculates the quantity and timing for the four split injections, for each of the three calibration levels for injection pressure, and also manages the transition between the levels.

The two post injections are required to separate the functionality of increasing in-cylinder gas temperatures and the production of hydrocarbons. The first post injection is used to generate the higher in-cylinder gas temperature while simultaneously retaining the same engine torque output produced during normal (non-regeneration) engine operation. The second post injection is used to generate hydrocarbons by allowing unburnt fuel into the catalytic converter without producing increased engine torque.

DPF Air Management Module

The DPF air management module controls the following functions:

- EGR control
- Turbocharger boost pressure control
- Intake air temperature and pressure control.

During active regeneration, the EGR operation is disabled and the closed-loop activation of the turbocharger boost controller is calculated. The air management module controls the air in the intake manifold to a predetermined level of pressure and temperature. This control is required to achieve the correct in-cylinder conditions for stable and robust combustion of the post injected fuel.

The module controls the intake air temperature by actuating the EGR throttle and by adjustment of the turbocharger boost pressure control.

DPF Co-ordinator Module

The DPF co-ordinator module reacts to a regeneration request from the supervisor module by initiating and co-ordinating the following DPF regeneration requests:

- • EGR cut-off
- • Turbocharger boost pressure control
- • Engine load increase
- • Control of air pressure and temperature in the intake manifold
- • Fuel injection control.

When the supervisor module issues a regeneration request, the co-ordinator module requests EGR cut-off and a regeneration specific turbocharger boost pressure control. It then waits for a feedback signal from the EGR system confirming that the EGR valve is closed.

When the EGR valve is closed, the co-ordinator module initiates requests to increase engine load by controlling the intake air temperature and pressure.

Once confirmation is received that intake conditions are controlled or a calibration time has expired, the co-ordinator module then changes to a state awaiting an accelerator pedal release manoeuvre from the driver. If this occurs or a calibration time has expired, the co-ordinator module generates a request to control fuel injections to increase exhaust gas temperature.

Component Description

FRONT SECTION

The front section comprises two catalytic converters. Each catalytic converter has an welded inlet pipe which is curved through 90 degrees. The outer end of the pipe is fitted with a flange which mates with the turbocharger for each bank of cylinders. Three holes in each flange locate on studs in the mating flange on the turbocharger and is secured with 3 flanged nuts. The base of each catalytic converter has an outlet pipe which is fitted with a cone. Two curved pipes from the front of the DPF locate over the outlet pipe on each catalytic converter and are sealed with a gasket against the cone. The joint is compressed and sealed with a clamp.

The curved pipes are welded to the front inlet cone which forms part of the DPF body. The curved pipe has an inner pipe which is secured in the outer pipe by 2 crimped indentations. The DPF inlet cone has 2 bosses which provide for the connection of a DPF temperature sensor and the high pressure pipe for the differential pressure sensor. The DPF is oval in shape and is closed at the rear by an outlet cone with 2 welded short pipes. The **LH (left-hand)** pipe has a bosses which allows for the attachment of the low pressure pipe for the differential pressure sensor. The 2 pipes are held together by a welded hanger brackets which supports the front section of the exhaust system on 2 mounting rubbers.

REAR SECTION

The 2 pipes from the DPF connect into 2 pipes which are welded to the front of the center resonator silencer. The resonator silencer is oval in shape and houses 2 perforated tubes separated by a baffle plate. Exhaust gasses exit the resonator silencer via one of 2 outlet pipes. The outlet pipes are braced together with a bracket and also each have a welded hanger bracket which allow the rear section to be supported on mounting rubbers.

The 2 rear silencers each have a welded inlet pipe which mate with the 2 outlet pipes from the center resonator silencer and are each secured with a clamp. The inlet pipes each have a welded hanger bracket which support each rear silencer at the rear of the vehicle on mounting rubbers. The fabricated rear silencers have 3 perforated tubes which are supported on 2 perforated baffle plates. The exhaust gasses are expelled from the rear silencer via a single outlet pipe. The outlet pipe from each silencer has a welded hanger bar which support the rear silencer on mounting rubbers. The outlet pipe is fitted with a welded outlet which is covered with a polished stainless steel finisher.

CATALYTIC CONVERTERS

The oxidizing catalytic converters are fitted in the front section of each exhaust system, after the pre-catalyst exhaust gas temperature sensor. The pre and post catalyst exhaust gas temperature sensors are used by the engine management system to monitor the DPF for regeneration purposes.

The engine management system provides accurately metered quantities of fuel to the combustion chambers to ensure the most efficient use of fuel and to minimise the exhaust emissions. To further reduce the carbon monoxide and hydrocarbons content of the exhaust gases, a catalytic converter is integrated into each front pipe of the exhaust system. In the catalytic converter the exhaust gases are passed through honeycombed ceramic elements coated with a special surface treatment called 'washcoat'. The washcoat increases the surface area of the ceramic elements by a factor of approximately 7000. On top of the washcoat is a coating containing platinum and palladium, which are the active constituents for converting harmful emissions into inert by-products. The platinum and palladium add oxygen to the carbon monoxide and the hydrocarbons in the exhaust gases, to convert them into carbon dioxide and water respectively.

DIESEL PARTICULATE FILTER (DPF)

6	DPF
7	DPF temperature sensor

The DPF system reduces diesel particulate emissions to negligible levels to meet current European stage 4 emission standards. The particulate emissions are the black fumes emitted from the diesel engine under certain load conditions. The emissions are a complex mixture of solid and liquid components with the majority of the particulates being carbon microspheres on which hydrocarbons from the engine's fuel and lubricant condense.

The DPF is located in the exhaust system, downstream of the catalytic converters. A major feature of the DPF is its ability for regeneration. Regeneration is the burning of particulates trapped by the filter to prevent obstruction to the free flow of exhaust gasses. The regeneration process takes place at calculated intervals and is not noticeable by the driver of the vehicle. Regeneration is most important, since an overfilled filter can damage the engine through excessive exhaust back pressure and can itself be damaged or destroyed. The material trapped in the filter is in the most part carbon particles with some absorbed hydrocarbons.

The DPF system comprises the following components:

- Diesel particulate filter
- DPF control software incorporated into the [ECM \(engine control module\)](#)
- Exhaust gas temperature sensors
- Differential pressure sensor.

A

B

C

E68716

ItemDescription

A	Front face showing alternate closed cells
B	Side view showing exhaust gas flow through the filter and particulate build up
C	Rear face showing alternate closed cells

The DPF uses a filter technology based on a filter with a catalytic coating. The DPF is made from silicon carbide housed in a steel container and has excellent thermal shock resistance and thermal conductivity properties. The DPF is designed for the engine's operating requirements to maintain the optimum back pressure requirements.

The porous surface of the filter consists of a number of small parallel channels positioned in the longitudinal direction of the exhaust system. Adjacent channels in the filter are alternately plugged at the end. This design forces the exhaust gasses to flow through the porous filter walls, which act as the filter medium. Particulate matter which are too big to pass through the porous surface are collected and stored in the channels.

The collected particulate matter, if not removed, can create an obstruction to exhaust gas flow. The particles are removed by a regeneration process which oxidizes the particles.

DPF regeneration is controlled by the temperature of the exhaust gasses and the DPF. The DPF includes a wash coat to the filter surface which comprises platinum and other active components and is similar to the catalytic converter. At certain exhaust gas and DPF temperatures the wash coat promotes combustion of the particles in addition to oxidizing carbon monoxide and hydrocarbon emissions.

The exhaust gas and DPF temperatures are controlled by the DPF software located in the ECM. The DPF software monitors the load status of the DPF based on driving style, distance travelled and signals from the differential pressure sensor and temperature sensors. When the particulate loading of the DPF reaches predetermined levels, the DPF is actively regenerated by adjusting, in conjunction with the ECM, various engine control functions such as:

- fuel injection
- intake air throttle
- exhaust gas recirculation
- turbocharger boost pressure control.

The regeneration process is possible because of the flexibility of the common-rail fuel injection engine which provides precise control of fuel flow, fuel pressure and injection timing which are essential requirements to promote the efficient regeneration process. Two processes are used to regenerate the DPF; passive and active.

DIFFERENTIAL PRESSURE SENSOR

E68718

ItemDescription

1	Low pressure connection
2	High pressure connection
3	Electrical connector

The differential pressure sensor is located in the engine compartment, on the lower RH (right-hand) side of the secondary bulkhead. The sensor is secured with 2 screws.

The differential pressure sensor is used by the DPF software to monitor the condition of the DPF. Two pipe connections on the sensor are connected by pipes to the inlet and outlet ends of the DPF. The pipes allow the sensor to measure the inlet (high) and outlet (low)

pressures of the DPF.

As the amount of particulates trapped by the DPF increases, the pressure at the inlet side of the DPF increases in comparison to the DPF outlet. The DPF software uses this comparison, in conjunction with other data, to calculate the accumulated amount of trapped particulates.

By measuring the pressure difference between the DPF inlet and outlet and the DPF temperature, the DPF software can determine if the DPF is becoming blocked and requires regeneration.

DIFFERENTIAL PARTICULATE FILTER TEMPERATURE SENSORS

Five temperature sensors are used in the DPF system. Two temperature sensors are located in the inlet and outlet sides of each catalytic converter and the fifth sensor is located in the front of the DPF.

The sensors measure the temperature of exhaust gas entering and exiting the catalytic converters and before it passes through the DPF and provides the information needed to calculate the DPF temperature.

The information is used, in conjunction with other data, to estimate the amount of accumulated particulates and to control the DPF temperature.

INSTRUMENT CLUSTER INDICATIONS

For drivers who make regular short journeys at low speeds, it may not be possible to efficiently regenerate the DPF. In this case, the DPF software will detect a blockage of the DPF from signals from the differential pressure sensor and will alert the driver as follows.

When the DPF becomes full the driver will be alerted to this condition by a message 'DPF FULL' accompanied by a handbook symbol. As detailed in the Owners Handbook, the driver should drive the vehicle until the engine is at its normal operating temperature and then drive for a further 20 minutes at speeds of not less than 30 mph (48 km/h). Successful regeneration of the DPF is indicated to the driver by the 'DPF FULL' message no longer being displayed.

If the DPF software detects that the DPF is still blocked, the message will change to 'DPF FULL VISIT DEALER', the driver should take the vehicle to an authorized dealer to have the DPF force regenerated.

DIESEL PARTICULATE FILTER SIDE EFFECTS

The following section details some side effects caused by the active regeneration process.

Engine Oil Dilution

Engine oil dilution can occur due to small amounts of fuel entering the engine crankcase during the post-injection phases. This has made it necessary to introduce a calculation based on driving style to reduce oil service intervals if necessary. The driver is alerted to the oil service by a message in the instrument cluster.

The DPF software monitors the driving style, the frequency of the active regeneration and duration. Using this information a calculation can be made on the engine oil dilution. When the DPF software calculates the engine oil dilution has reached a predetermined threshold (fuel being 7% of engine oil volume) a service message is displayed in the instrument cluster.

Depending on driving style, some vehicles may require an oil service before the designated interval. If a service message is displayed, the vehicle will be required have a full service and the service interval counter will be reset.

Fuel Consumption

During the active regeneration process of the DPF, there will be an increase in fuel consumption. However, because active regeneration occurs infrequently and for limited periods of time, the overall effect on fuel consumption is approximately 2%. The additional fuel used during the active regeneration process is accounted for in the instantaneous and average fuel consumption displays in the instrument cluster.

Exhaust System - TDV6 2.7L Diesel - Exhaust System

Diagnosis and Testing

Principles of Operation

For a detailed description of the diesel engine exhaust system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (309-00A)

Exhaust System (Description and Operation),
Exhaust System (Description and Operation),
Exhaust System (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical
<ul style="list-style-type: none"> ● Leaks ● Metal fatigue ● Pipes, mufflers and catalytic converters ● Joints ● Mountings ● Clearance around components

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Excessively noisy/leaking exhaust	<ul style="list-style-type: none"> ● Exhaust system/components 	Inspect exhaust system, refer to Visual Inspection above. Rectify leaks and install new components as required. Refer to Removal and Installation instructions in this section
Loss of power	<ul style="list-style-type: none"> ● Restricted exhaust system ● Fuel system ● Ignition system ● Electronic engine control 	Install new exhaust components as required. Refer to Removal and Installation instructions in this section. Check for fuel, ignition and electronic engine control DTCs and refer to the relevant DTC Index

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

- NOTE: If the module or a component is suspect and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).
- NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Exhaust System - TDV6 2.7L Diesel - Catalytic Converter

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

 **CAUTION:** Make sure that the exhaust system is supported with a suitable transmission stand.

Raise and support the vehicle.

2. Remove the engine rear undershield.
For additional information, refer to: Engine Rear Undershield (501-02, Removal and Installation).
3. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).

4. **NOTE:** Right-hand shown, left-hand similar.

Disconnect the diesel particulate filter (DPF) wiring harness electrical connectors.

5. **NOTE:** Right-hand shown, left-hand similar.

Release the catalyst monitor sensor wiring harness.

6.  **CAUTION:** Make sure that the catalytic converter is supported using suitable retaining straps.

• **NOTE:** Right-hand shown, left-hand similar.

Detach the catalytic converter.

- Remove and discard the retaining nuts.

7. NOTE: Right-hand shown, left-hand similar.

Loosen the catalytic converter to diesel particulate filter (DPF) retaining clamp.

8.  CAUTION: Make sure that the catalytic converter is supported using suitable retaining straps.

• NOTE: Right-hand shown, left-hand similar.

Remove the catalytic converter.

- Remove and discard the gasket.

9. NOTE: Do not disassemble further if the component is removed for access only.

Remove the catalytic converter temperature sensors.

Installation

1. Install the catalytic converter temperature sensors.

- Tighten to 35 Nm.

E96854

2.  CAUTION: Jointing compound must not be used forward of the catalytic converter.

- NOTE: Right-hand shown, left-hand similar.

Loosely install the catalytic converter.

- Install a new gasket.
- Install new nuts.

E97072

3. NOTE: Right-hand shown, left-hand similar.

Tighten the catalytic converter to DPF retaining clamp.

- Tighten to 55 Nm.

E97073

4.  CAUTION: Make sure that the catalytic converter is supported using suitable retaining straps.

- NOTE: Right-hand shown, left-hand similar.

Attach the catalytic converter.

- Tighten to 22 Nm.

E97074

5. NOTE: Right-hand shown, left-hand similar.

Attach the catalyst monitor sensor wiring harness.

6. NOTE: Right-hand shown, left-hand similar.

Connect the DPF wiring harness electrical connectors.

7. NOTE: For NAS vehicles only.

If required, carry out a long drive cycle.

For additional information, refer to: Powertrain Control Module (PCM) Long Drive Cycle Self-Test (303-14C, General Procedures).

Exhaust System - TDV6 2.7L Diesel - Exhaust System

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

2. Remove both muffler and tailpipes.
For additional information, refer to: Muffler and Tailpipe (309-00, Removal and Installation).
3. Remove the engine rear undershield.
For additional information, refer to: Engine Rear Undershield (501-02, Removal and Installation).
4. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
5. **NOTE:** Right-hand shown, left-hand similar.

Loosen the catalytic converter to diesel particulate filter (DPF) retaining clamp.

E63616

6. Disconnect the DPF wiring harness electrical connector.

E63614

7.  **CAUTION:** Make a note of the connection orientation of the high and low pressure hoses to the sensor ports. Make sure the hoses are located to the correct sensor port when installed. Failure to follow these instructions may result in damage to the vehicle.

Disconnect the high and low pressure hoses from the DPF differential pressure sensor.

E63615

8. Remove the rear crossmember.

9. Remove the rear subframe crossbrace.

10.  CAUTION: Make sure that the exhaust system is supported with a suitable transmission stand.

Release the DPF mount bracket.

- Remove and discard the 4 nuts.

11. With assistance, remove the exhaust system.

- Discard the gaskets.

Installation

1. To install, reverse the removal procedure.

E64497

2. Tighten to 10 Nm.

E63613

3. Tighten to 62 Nm.

E96680

4. Tighten to 30 Nm.

E96679

5. Tighten to 9 Nm.

E63616

Exhaust System - TDV6 2.7L Diesel - Diesel Particulate Filter (DPF)

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise the vehicle.

2. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).

3. Remove the engine rear undershield.
For additional information, refer to: Engine Rear Undershield (501-02, Removal and Installation).

4. Disconnect the diesel particulate filter (DPF) wiring harness electrical connector.

E63614

E63615

5.  **CAUTION:** Make a note of the connection orientation of the high and low pressure hoses to the sensor ports. Make sure the hoses are located to the correct sensor port when installed. Failure to follow these instructions may result in damage to the vehicle.

Disconnect the high and low pressure hoses from the DPF differential pressure sensor.

6. Loosen the DPF to center muffler retaining clamps.

E64486

7. Remove the DPF mount bracket.

- Remove and discard the 4 nuts.

8. With assistance, remove the DPF.

Installation

1. To install, reverse the removal procedure.
2. Tighten to 9 Nm.

3. NOTE: Install a new gasket.

- NOTE: Right-hand shown, left-hand similar.

Tighten to 11 Nm.

4. Tighten to 55 Nm.

E64486

Exhaust System - TDV6 2.7L Diesel - Diesel Particulate Filter (DPF) Differential

Pressure Sensor

Removal and Installation

Removal

1. Disconnect the battery ground cable.
2. Disconnect the diesel particulate filter (DPF) differential pressure sensor electrical connector.

3.  **CAUTION:** Make a note of the connection orientation of the high and low pressure hoses to the sensor ports. Make sure the hoses are located to the correct sensor port when installed. Failure to follow these instructions may result in damage to the vehicle.

Disconnect the high and low pressure hoses from the DPF differential pressure sensor.

4. Remove the DPF differential pressure sensor.

Installation

1. To install, reverse the removal procedure.
 - Tighten to 2 Nm.

Exhaust System - TDV6 2.7L Diesel - Front Muffler

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1. Raise the vehicle.
2. Remove the muffler and tailpipe.
For additional information, refer to: Muffler and Tailpipe (309-00, Removal and Installation).
3. Repeat the above procedure on the opposite side.
4. Remove the engine rear undershield.
5. Remove the support bracket.
 - Remove the 4 bolts.

6. Remove the rear crossmember.

7. Remove the rear subframe crossbrace.

8. Release the exhaust clamps.

9. With assistance, remove the front muffler.

- Release both front muffler hanger insulators.

Installation

1.  **CAUTION:** The hanger insulators are constructed of a special material. Use only the correct specification insulators.

• **NOTE:** Check the hanger insulators for damage or fatigue. Install new hangers if required

To install, reverse the removal procedure.

- Tighten the catalytic converter retaining clamp to 55 Nm.
- Tighten to 62 Nm.
- Tighten to 30 Nm.
- Tighten to 6 Nm.

Exhaust System - TDV6 2.7L Diesel - Rear Muffler

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

• **NOTE:** Removal steps in this procedure may contain installation details.

1.  **WARNING:** Make sure to support the vehicle with axle stands.
Raise and support the vehicle.

2.  **CAUTION:** Make sure that these components are installed to the noted removal position.

Torque:

M8 25 Nm

M10 55 Nm

E95673

Installation

1. To install, reverse the removal procedure.

Exhaust System - V6 3.0L Petrol - Exhaust System - Overview

Description and Operation

OVERVIEW

The 3.0L V6 exhaust system is fabricated from stainless steel and is supplied as 5 separate assemblies. The system is very similar in design to the system used on the 4.2L V8 naturally aspirated engine variant.

The front section comprises 2 separate assemblies; [LH \(left-hand\)](#) and [RH \(right-hand\)](#), incorporating a catalytic converter for each bank of cylinders. The rear section comprises of 3 separate sections incorporating a center resonator silencer and a rear silencer.

The system is attached to the underside of the body with mounting rubbers which are located on mild steel hanger bars that are welded to the system. The mounting rubbers locate on corresponding hangers which are welded or bolted to the underside of the vehicle body.

Exhaust System - V6 3.0L Petrol - Exhaust System - System Operation and Component Description

Description and Operation

System Operation

CATALYTIC CONVERTERS

In the catalytic converters, the exhaust gases are passed through honeycombed ceramic elements coated with a special surface treatment called 'washcoat'. The washcoat increases the surface area of the ceramic elements by a factor of approximately 7000. On top of the washcoat is a coating containing palladium and rhodium, which is the active constituent for converting harmful emissions into inert by-products. The palladium and rhodium add oxygen to the carbon monoxide and the hydrocarbons in the exhaust gases, to convert them into carbon dioxide and water respectively.

Component Description

FRONT SECTION

The front section comprises two separate pipes, each incorporating a catalytic converter. Each catalytic converter has a welded inlet pipe with a flange. The inlet pipe is flared into a cone which mates with the exhaust manifold. The flange has two holes which locate on studs in the exhaust manifold and is secured with flanged nuts. Each catalytic converter is fitted with a pre and post catalyst [HO2S \(heated oxygen sensor\)](#).

Each catalytic converter has a curved outlet pipe which mates with the respective inlet pipe for the applicable resonator silencer. The joint is secured compressed and sealed with a clamp.

REAR SECTION

The 2 inlet pipes each connect into a separate resonator silencer. Each resonator silencer is cylindrical in shape and houses 2 perforated tubes separated by 2 baffle plates. Exhaust gasses exit each resonator silencer via an outlet pipe. The 2 outlet pipes are joined together behind the resonator silencers with a cross over pipe. Each pipe also has a welded hanger bracket which allow the rear section to be supported on mounting rubbers. A further bracket is welded to each pipe which braces the 2 pipes together.

The 2 rear silencers each have a welded inlet pipe which mate with the outlet pipes from the resonator silencers and are each secured with a clamp. The inlet pipes each have a welded hanger bracket which support each rear silencer at the rear of the vehicle on mounting rubbers. The fabricated rear silencers have 3 perforated tubes which are supported on 3 perforated baffle plates. The exhaust gasses are expelled from the rear silencer via a single outlet pipe. The outlet pipe from each silencer has a welded hanger bar which support the rear silencer on mounting rubbers. The outlet pipe is fitted with a welded outlet which is covered with a polished stainless steel finisher.

CATALYTIC CONVERTERS

A catalytic converter is fitted in each front section of the exhaust system. Each catalytic converter is fitted with 2 [HO2S](#).

The [HO2S](#) monitors the exhaust gasses leaving the engine. The [ECM \(engine control module\)](#) uses this information to provide accurately metered quantities of fuel to the combustion chambers to ensure the most efficient use of fuel and to minimize the exhaust emissions.

Exhaust System - V6 3.0L Petrol - Exhaust System

Diagnosis and Testing

Principle of Operation

For a detailed description of the exhaust system, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

- [Exhaust System](#) (309-00B Exhaust System - V6 3.0L Petrol, Description and Operation),
- [Exhaust System](#) (309-00B Exhaust System - V6 3.0L Petrol, Description and Operation),
- [Exhaust System](#) (309-00B Exhaust System - V6 3.0L Petrol, Description and Operation),
- [Exhaust System](#) (309-00C Exhaust System - V8 4.2L Petrol/V8 S/C 4.2L Petrol, Description and Operation),
- [Exhaust System](#) (309-00C Exhaust System - V8 4.2L Petrol/V8 S/C 4.2L Petrol, Description and Operation),
- [Exhaust System](#) (309-00C Exhaust System - V8 4.2L Petrol/V8 S/C 4.2L Petrol, Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern by operating the system.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical
<ul style="list-style-type: none"> ● Leaks ● Metal fatigue ● Pipes, mufflers and catalytic converters ● Joints ● Mountings ● Clearance around components

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the concern is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Excessively noisy/leaking exhaust	<ul style="list-style-type: none"> ● Exhaust system/components 	Inspect exhaust system, refer to Visual Inspection above. Rectify leaks and install new components as required. Refer to Removal and Installation instructions in this section
Loss of power	<ul style="list-style-type: none"> ● Restricted exhaust system ● Exhaust sound enhancement valve stuck closed ● Fuel system ● Ignition system ● Electronic engine control 	Inspect exhaust system, refer to Visual Inspection above. Install new exhaust components as required. Refer to Removal and Installation instructions in this section. Check for fuel, ignition and electronic engine control system DTCs and refer to the relevant DTC Index

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

- NOTE: If the module or a component is suspect and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the Check and installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).
- NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
P003100	HO2S Heater Control Circuit Low (Bank 1, Sensor 1)	<ul style="list-style-type: none"> ● HO2S heater circuit - circuit fault ● HO2S heater failure 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Exhaust System - V6 3.0L Petrol - Catalytic Converter

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise the vehicle.

2. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).

3. Remove the heated oxygen sensor (HO2S).

1. Release the electrical connector from the bracket.
2. Disconnect the electrical connector.
3. Remove the HO2S.

4. Remove the catalyst monitor sensor.

- Release the electrical connector from the bracket.
- Disconnect the electrical connector.
- Remove the catalyst monitor sensor.

5. Loosen the catalytic converter exhaust clamps and release the front silencer.

6. Release the catalytic converter.

7. Remove the catalytic converter.

Installation

1. To install, reverse the removal procedure.
2. Tighten to 40 Nm.

3. Tighten to 55 Nm.

4. Install catalyst monitor sensor and tighten to 40 Nm.

5. Install the HO2S and tighten to 40 Nm.

6. NOTE: For NAS vehicles only.

If required, carry out a long drive cycle.

For additional information, refer to: Powertrain Control Module (PCM)
Long Drive Cycle Self-Test (303-14C, General Procedures).

Exhaust System - V6 3.0L Petrol - Exhaust System

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

 **CAUTION:** Make sure that the exhaust system is supported with a suitable transmission stand.

Raise and support the vehicle.

2. Remove both muffler and tailpipes.
3. Remove the engine rear undershield.
4. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
5. Remove the rear crossmember.

6. Remove the rear subframe crossbrace.

- Remove the rear subframe crossbrace.

7. **NOTE:** Right-hand shown, left-hand similar.

Disconnect the heated oxygen sensor (HO2S) electrical connector.

8. NOTE: Right-hand shown, left-hand similar.

Disconnect the catalyst monitor sensor electrical connector.

9. NOTE: Right-hand shown, left-hand similar.

Detach the catalytic converter.

10. NOTE: Check the hanger insulators for damage or fatigue. Install new hangers if required

Release the 2 exhaust hangers.

11. With assistance, remove the exhaust system.

Installation

1. To install, reverse the removal procedure.

2. Tighten to 40 Nm.

3. Tighten to 30 Nm.

4. Tighten to 62 Nm.

Exhaust System - V6 3.0L Petrol - Front Muffler

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1. Raise the vehicle.
2. Remove the muffler and tailpipe.
For additional information, refer to: Muffler and Tailpipe (309-00, Removal and Installation).
3. Repeat the above procedure on the opposite side.
4. Remove the engine rear undershield.
5. Remove the support bracket.
 - Remove the 4 bolts.

6. Remove the rear crossmember.

7. Remove the rear subframe crossbrace.

8. Release the exhaust clamps.

9. With assistance, remove the front muffler.

- Release both front muffler hanger insulators.

Installation

1.  **CAUTION:** The hanger insulators are constructed of a special material. Use only the correct specification insulators.

• **NOTE:** Check the hanger insulators for damage or fatigue. Install new hangers if required

To install, reverse the removal procedure.

- Tighten the catalytic converter retaining clamp to 55 Nm.
- Tighten to 62 Nm.
- Tighten to 30 Nm.
- Tighten to 6 Nm.

Exhaust System - V6 3.0L Petrol - Rear Muffler

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

• **NOTE:** Removal steps in this procedure may contain installation details.

1.  **WARNING:** Make sure to support the vehicle with axle stands.
Raise and support the vehicle.

2.  **CAUTION:** Make sure that these components are installed to the noted removal position.

Torque:

M8 25 Nm

M10 55 Nm

Installation

1. To install, reverse the removal procedure.

Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Exhaust System - Overview

Description and Operation

OVERVIEW

The 4.2L V8 exhaust system is fabricated from stainless steel and is supplied as 5 separate assemblies. The 4.2L V8 naturally aspirated system is similar in design to the system used on the 3.0L V6 engine variant. The 4.2L V8 supercharged system is also similar but uses a different design of center resonator silencer.

The front section comprises 2 separate assemblies ([LH \(left-hand\)](#) and [RH \(right-hand\)](#)) incorporating a catalytic converter for each bank of cylinders. The rear section also comprises 3 separate sections. Each section incorporates a center resonator silencer and a rear silencer.

The system is attached to the underside of the body with mounting rubbers which are located on mild steel hanger bars that are welded to the system. The mounting rubbers locate on corresponding hangers which are welded or bolted to the underside of the vehicle body.

Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Exhaust System - System Operation and Component Description

Description and Operation

System Operation

CATALYTIC CONVERTERS

In the catalytic converters, the exhaust gases are passed through honeycombed ceramic elements coated with a special surface treatment called 'washcoat'. The washcoat increases the surface area of the ceramic elements by a factor of approximately 7000. On top of the washcoat is a coating containing palladium and rhodium, which are the active constituents for converting harmful emissions into inert by-products. The palladium and rhodium add oxygen to the carbon monoxide and the hydrocarbons in the exhaust gases, to convert them into carbon dioxide and water respectively.

Component Description

FRONT SECTION - NORMALLY ASPIRATED ENGINES

The front section comprises two separate pipes, each incorporating a catalytic converter. Each catalytic converter has a welded inlet pipe with a flange. The inlet pipe is flared into a cone which mates with the exhaust manifold. The flange has two holes which locate on studs in the exhaust manifold and is secured with flanged nuts. Each catalytic converter is fitted with a pre and post catalyst [HO2S \(heated oxygen sensor\)](#).

Each catalytic converter has a curved outlet pipe which mates with the respective inlet pipe for the applicable resonator. The joint is secured compressed and sealed with a clamp.

FRONT SECTION - SUPERCHARGED ENGINES

The front section comprises two separate pipes, each incorporating a catalytic converter. Each catalytic converter has a welded inlet pipe with a flange. The inlet pipe is flared into a cone which mates with the exhaust manifold. The flange has two holes which locate on studs in the exhaust manifold and is secured with flanged nuts. Each catalytic converter is fitted with a pre and post catalyst [HO2S](#).

Each catalytic converter has a curved outlet pipe which mates with the respective inlet pipe for the resonator. The joint is secured compressed and sealed with a clamp.

REAR SECTION - NORMALLY ASPIRATED ENGINES

The 2 inlet pipes each connect into a separate resonator silencer. Each resonator silencer is cylindrical in shape and houses 2 perforated tubes separated by 2 baffle plates. Exhaust gasses exit each resonator silencer via an outlet pipe. The 2 outlet pipes are joined together behind the resonators with a cross over pipe. Each pipe also has a welded hanger bracket which allow the rear section to be supported on mounting rubbers. A further bracket is welded to each pipe which braces the 2 pipes together.

The 2 rear silencers each have a welded inlet pipe which mate with the outlet pipes from the resonator silencers and are each secured with a clamp. The inlet pipes each have a welded hanger bracket which support each rear silencer at the rear of the vehicle on mounting rubbers. The fabricated rear silencers have 2 perforated tubes which are supported on 2 perforated baffle plates. The exhaust gasses are expelled from the rear silencer via a single outlet pipe. The outlet pipe from each silencer has a welded hanger bar which support the rear silencer on mounting rubbers. The outlet pipe is fitted with a welded outlet which is covered with a polished stainless steel finisher.

REAR SECTION - SUPERCHARGED ENGINES

The 2 inlet pipes each connect into a single resonator silencer housing perforated tubes separated by 2 baffle plates. Exhaust gasses exit the resonator silencer via 2 outlet pipes. Each outlet pipe has a welded hanger bracket which allow the rear section to be supported on mounting rubbers. A further bracket is welded to each pipe which braces the 2 pipes together.

The 2 rear silencers each have a welded inlet pipe which mate with the outlet pipes from the resonator silencer and are each secured with a clamp. The inlet pipes each have a welded hanger bracket which support each rear silencer at the rear of the vehicle on mounting rubbers. The fabricated rear silencers have 2 perforated baffle tubes which are supported on 2 perforated baffle plates. The exhaust gasses are expelled from the rear silencer via a single outlet pipe. The outlet pipe from each silencer has a welded hanger bar which support the rear silencer on mounting rubbers. The outlet pipe is fitted with a welded outlet which is covered with a polished stainless steel finisher.

CATALYTIC CONVERTERS

A catalytic converter is fitted in each front section of the exhaust system. Each catalytic converter is fitted with 2 [HO2S](#).

The [HO2S](#) monitors the exhaust gasses leaving the engine. The [ECM \(engine control module\)](#) uses this information to provide accurately metered quantities of fuel to the combustion chambers to ensure the most efficient use of fuel and to minimize the exhaust emissions.

Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Exhaust System

Diagnosis and Testing

Principle of Operation

For a detailed description of the exhaust system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (309-00 Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

[Exhaust System](#) (Description and Operation),
[Exhaust System](#) (Description and Operation),
[Exhaust System](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. Verify the customer concern by operating the system.
2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical
<ul style="list-style-type: none"> ● Leaks ● Metal fatigue ● Pipes, mufflers and catalytic converters ● Joints ● Mountings ● Clearance around components

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the concern is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Excessively noisy/leaking exhaust	<ul style="list-style-type: none"> ● Exhaust system/components 	Inspect exhaust system, refer to Visual Inspection above. Rectify leaks and install new components as required. Refer to Removal and Installation instructions in this section
Loss of power	<ul style="list-style-type: none"> ● Restricted exhaust system ● Exhaust sound enhancement valve stuck closed ● Fuel system ● Ignition system ● Electronic engine control 	Inspect exhaust system, refer to Visual Inspection above. Install new exhaust components as required. Refer to Removal and Installation instructions in this section. Check for fuel, ignition and electronic engine control system DTCs and refer to the relevant DTC Index

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: If the module or a component is suspect and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the Check and installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action

Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Catalytic Converter

Removal and Installation

Removal

WARNING: Observe due care when working near a hot exhaust system.

- WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise the vehicle.

- Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
- Remove the heated oxygen sensor (HO2S).
 - Release the electrical connector from the bracket.
 - Disconnect the electrical connector.
 - Remove the HO2S.

VUJ0000252

- Remove the catalyst monitor sensor.
 - Release the electrical connector from the bracket.
 - Disconnect the electrical connector.
 - Remove the catalyst monitor sensor.

VUJ0000246

- Loosen the catalytic converter exhaust clamps and release the front silencer.

VUJ0004984

6. Release the catalytic converter.

7. Remove the catalytic converter.

Installation

1. To install, reverse the removal procedure.
2. Tighten to 40 Nm.

3. Tighten to 55 Nm.

4. Install catalyst monitor sensor and tighten to 40 Nm.

5. Install the HO2S and tighten to 40 Nm.

6. NOTE: For NAS vehicles only.

If required, carry out a long drive cycle.
For additional information, refer to: Powertrain Control Module (PCM) Long Drive Cycle Self-Test (303-14C, General Procedures).

Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Exhaust System

Removal and Installation

Removal

 **WARNING:** Observe due care when working near a hot exhaust system.

1.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

 **CAUTION:** Make sure that the exhaust system is supported with a suitable transmission stand.

Raise and support the vehicle.

2. Remove both muffler and tailpipes.
3. Remove the engine rear undershield.
4. Remove the air deflector.
For additional information, refer to: Air Deflector (501-02, Removal and Installation).
5. Remove the rear crossmember.

6. Remove the rear subframe crossbrace.

- Remove the rear subframe crossbrace.

7. **NOTE:** Right-hand shown, left-hand similar.

Disconnect the heated oxygen sensor (HO2S) electrical connector.

8. NOTE: Right-hand shown, left-hand similar.

Disconnect the catalytic monitor sensor electrical connector.

9. NOTE: Right-hand shown, left-hand similar.

Detach the catalytic converter.

10. NOTE: Check the hanger insulators for damage or fatigue. Install new hangers if required

Release the 2 exhaust hangers.

11. With assistance, remove the exhaust system.

Installation

1. To install, reverse the removal procedure.

2. Tighten to 40 Nm.

3. Tighten to 30 Nm.

4. Tighten to 62 Nm.

Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Front Muffler

Removal and Installation

Removal

WARNING: Observe due care when working near a hot exhaust system.

1. Raise the vehicle.
2. Remove the muffler and tailpipe.
For additional information, refer to: Muffler and Tailpipe (309-00, Removal and Installation).
3. Repeat the above procedure on the opposite side.
4. Remove the engine rear undershield.
5. Remove the support bracket.
 - Remove the 4 bolts.

- Remove the 4 bolts.

6. Remove the rear crossmember.

7. Remove the rear subframe crossbrace.

8. Release the exhaust clamps.

9. With assistance, remove the front muffler.

- Release both front muffler hanger insulators.

Installation

1.  CAUTION: The hanger insulators are constructed of a special material. Use only the correct specification insulators.

• NOTE: Check the hanger insulators for damage or fatigue. Install new hangers if required

To install, reverse the removal procedure.

- Tighten the catalytic converter retaining clamp to 55 Nm.
- Tighten to 62 Nm.
- Tighten to 30 Nm.
- Tighten to 6 Nm.

Exhaust System - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Rear Muffler

Removal and Installation

Removal

WARNING: Observe due care when working near a hot exhaust system.

- NOTE: Removal steps in this procedure may contain installation details.

General Procedures

All vehicles

• NOTE: This procedure is for the installation of the adaptor into the fuel line due to the removal of the schraeder valve from the fuel line.

1. WARNINGS:

Place the vehicle in a quarantined area and arrange "No Smoking/Petrol Fumes" signs about the vehicle.

Before any work is carried out on the fuel system, ground the vehicle to earth and maintain the ground connection until the work is complete.

Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

Do not carry or operate cellular phones when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

The fuel system remains pressurized for a long time after the ignition is switched off. The fuel pressure must be relieved before attempting any repairs. Failure to follow these instructions may result in personal injury.

This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

After carrying out repairs, the fuel system must be checked visually for leaks. Failure to follow these instructions may result in personal injury.

Disconnect the battery ground cable.

For additional information, refer to: Battery Disconnect (414-01, General Procedures).

2. Remove the engine cover.

Vehicles with 2.5L or 3.0L engine

3. Remove the air cleaner outlet pipe.

For additional information, refer to: Air Cleaner Outlet Pipe - VIN Range: N52048->N99999 (303-12A, Removal and Installation).

4. Detach the power steering fluid reservoir and reposition.

General Procedures

CAUTION: When depressurising the fuel system, make sure that there is no throttle input. Failure to follow this instruction may cause damage to the vehicle.

1. WARNINGS:

Place the vehicle in a quarantined area and arrange ' No Smoking/Petrol Fumes' signs about the vehicle.

The fuel system remains pressurized for a long time after the ignition is switched off. The fuel pressure must be relieved before attempting any repairs. Failure to follow these instructions may result in personal injury.

CAUTION: Make sure the engine is cold before this procedure is carried out. Failure to follow this instruction may result in damage to the vehicle.

Remove the fuel pump and sender unit fuse.

2. CAUTIONS:

When depressurising the fuel system, make sure that there is no throttle input. Failure to follow this instruction may cause damage to the vehicle.

Make sure that as soon as the vehicle is running roughly/misfiring that the engine is immediately switched off. Failure to follow this instruction may result in damage to the vehicle.

Start and run the engine until it runs roughly or starts misfiring.

3. Refit the fuel pump fuse.

4. Start and run the engine.

5. Read and clear stored DTC fault codes.

Fuel System - General Information - Low-Pressure Fuel System Bleeding TDV6 2.7L

Diesel

General Procedures

• WARNINGS:

Wait at least 30 seconds after the engine stops before commencing any repair to the high-pressure fuel injection system. Failure to follow this instruction may result in personal injury.

Before any work is carried out on the fuel system, ground the vehicle to earth and maintain the ground connection until the work is complete.

Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

After carrying out repairs, the fuel system must be checked visually for leaks. Failure to follow this instruction may result in personal injury.

If taken internally, do not induce vomiting, seek immediate medical attention. Failure to follow these instructions may result in personal injury.

If fuel contacts the eyes, flush the eyes with cold water or eyewash solution and seek immediate medical attention.

Wash hands thoroughly after fuel handling, as prolonged contact may cause irritation. Should irritation develop, seek medical attention.

This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

• CAUTIONS:

Diesel fuel injection equipment is manufactured to very precise tolerances and fine clearances. It is therefore essential that absolute cleanliness is observed when working with these components. Always install blanking plugs to any open orifices or lines. Failure to follow this instruction may result in foreign matter ingress to the fuel injection system.

This procedure must be carried out before the engine is attempted to be started, following removal or replacement of any fuel system component involving fuel line intrusion. Failure to follow this instruction will result in damage to the fuel injection pump.

• NOTE: This procedure is necessary if any low-pressure fuel system components are removed or replaced. These include the fuel filter, fuel lines, fuel tank or fuel cooler.

1. NOTE: If the ignition is switched on for more than 10 seconds without the engine starting the fuel pump will switch off to protect itself.

Switch ignition on for 10 seconds. The fuel pump in the fuel tank will be audible.

2. Switch the ignition off.

3. NOTE: Do not start the vehicle.

• NOTE: Allow 15 seconds between **each** ignition cycle (between each ignition **ON** and ignition **OFF**) to allow the fuel tank pump to pump fuel to the fuel injection pump correctly.

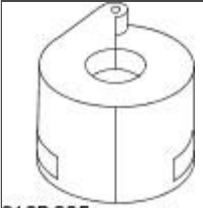

Switch the ignition on and off four times.

4. NOTE: The engine must be allowed to idle for two minutes to allow a full system bleed.

Crank the engine until it starts and allow to idle.

Fuel Tank and Lines - TDV6 2.7L Diesel - Fuel Tank and Lines - Overview

Description and Operation

OVERVIEW

The fuel tank houses an internal fuel lift pump, located in the fuel pump module. The lift pump is employed to provide a low-pressure supply to the common rail high pressure fuel system.

Two fuel level sensors are installed in either side of the saddle tank. The sensors are a MAPPS (magnetic passive position sensor) which provide a variable resistance to ground for the output from the fuel gauge.

Two fuel coolers are fitted to the vehicle. One is located in the low pressure side of the system in the fuel return line and is a fuel to air cooler. The second cooler, in the high pressure side, is located in the 'vee' of the engine block, and has a coolant system connection to aid heat transfer.

The fuel tank breather system consists of a ROV (roll over valve), fuel level vent valve and a fuel tank breather filter.

The fuel filter is a disposable canister type and is located on the left hand front inner wing turret.

• NOTE: The fuel fired additional heating system is discontinued, eliminating the dosing pump and pipework from the fuel tank and lines system.

Fuel Tank and Lines - TDV6 2.7L Diesel - Fuel Tank and Lines - System Operation and Component Description

Description and Operation

Control Diagram

E94670

ItemDescription

5	Fuel cooler (under vehicle)
6	Fuel injection pump
7	Distribution rail
8	Piezo injector
9	Fuel rail
10	Fuel cooler (engine)
11	Lift pump pressure regulator

System Operation

Diesel fuel is drawn from the tank by the internal electric lift pump. The fuel pressure regulator located in the fuel pump module assembly regulates the delivery pressure at approximately 0.5 bar to the transfer pump housed in the HPP (high pressure pump). A VCV (volume control valve) governs the amount of fuel supplied to the HPP (high-pressure pump).

The transfer and high pressure pump are driven directly by the engine. Due to the storage volume of the common rail, the injection pressure will remain practically constant over the complete duration of the injection process.

The HPP (high pressure pump) has a return pipe circuit which is separate from the injector return pipes.
 Refer to: Fuel Charging and Controls (303-04A, Description and Operation).

Component Description

FUEL TANK

E94663

ItemDescription

1	Fuel pump module
2	ROV (roll over valve)
3	Tank breather filter
4	Fuel level vent valve
5	Transfer pump module assembly
6	Fuel return pipe
7	Fuel supply to engine
8	Jet pump
9	LH (left-hand) fuel level sensor float
10	Internal fuel transfer pipes
11	RH (right-hand) fuel level sensor float
12	Fuel pick up pipe with integrated coarse filter

The fuel tank is a saddle type tank constructed of HDPE (high density polyethylene), a plastic blow molded material. The tank is located forward of the rear suspension and is mounted using two metal straps. The tank is a sealed unit with the only internal access being through the fuel pump module and transfer pump module flange apertures on the top of the tank.

The fuel pump module flange has a six pin external connector which provides the electrical connections for the fuel pump, low fuel level switch and the right hand fuel level sensor. A quick release connector provides for the connection of the fuel feed pipe.

The transfer pump module flange has a two pin external connector which provides the electrical connection for the left hand fuel level sensor. A quick release connector provides for the connection of the fuel return pipe.

Each flange is fitted with a collar, clamp and seal which locate in the tank apertures. An arrow on each flange must be aligned between two molded lines on the tank, adjacent to the fuel pump module or transfer pump flange aperture, to obtain the correct pump orientation. A collar is located over each flange and is secured with a clamp.

FUEL PUMP MODULE

E94664

ItemDescription

1	Fuel pick up pipe with integrated coarse filter
2	RH fuel level sensor
3	Lift pump pressure regulator
4	Electrical connector
5	Fuel pump module

The low pressure fuel lift pump is located in the fuel pump module and is designed with low level fuel pick-up features. The lift pump is employed to provide a low pressure supply, approximately 0.5 bar, to the common-rail high pressure fuel system and maintain an equal fuel level in both compartments of the saddle tank.

The lift pump operation is controlled by the [ECM \(engine control module\)](#), via the fuel pump relay located in the [RJB \(rear junction box\)](#). When the ignition is switched on the fuel pump operates for 25 seconds to build up fuel pressure. As engine cranking commences the fuel pump stops running until the engine starts. This function is employed to decrease load on the battery.

In cold conditions, 'waxing' of the fuel can occur. For this reason a coarse mesh filter is attached to the swirl pot inlet port at the bottom of the pump module.

A four pipe manifold connection is located next to the fuel pressure regulator at the top of the fuel pump module. One connection is the fuel pump outlet connection which feeds into the manifold. A second connection allows fuel at pump outlet pressure to flow back through the pump module housing from the manifold to the lower swirl pot area. The third connection feeds the pressure regulator and fuel delivery line. When the regulator has opened, due to excessive pump output pressure, fuel returns through the fourth manifold connection to the swirlpot.

The right hand fuel level sensor and low fuel level switch are mounted into the pump module housing.

FUEL LEVEL SENSORS

Left Hand Fuel Level Sensor

E94665

ItemDescription

1	Transfer pump module
2	Fuel cross-over pipes
3	Fuel level sensor float
4	Filter
5	Jet pump
6	Fuel level sensor

Two fuel level sensors are installed in either side of the saddle tank. One is mounted on the fuel pump module, the other is mounted on the transfer pump module in the other side of the fuel tank. The sensors are a MAPPS (magnetic passive position sensor) which provide a variable resistance to ground for the output from the fuel gauge. The sensor is sealed from the fuel preventing contamination of the contacts, increasing reliability. The fuel level sensors are connected to external electrical connectors on the underside of the fuel and transfer pump module flanges.

The sensor comprises a series of 51 film resistors mounted in an arc on a ceramic surface. The resistors are wired in series with individual contacts. A soft magnetic foil with 51 flexible contacts is mounted a small distance above the film resistors. A magnet, located below the ceramic surface, is attached to the sender unit float arm. As the float arm moves, the magnet follows the same arc as the film resistors. The magnet pulls the flexible contacts onto the opposite film resistor contacts forming an electrical circuit.

E44504

ItemDescription

1	Magnetic foil
2	Spacer
3	Ceramic surface
4	Magnet
5	Resistance film

The film resistors are arranged in a linear arc with resistance ranging from 51.2 to 992.11 Ohms. The electrical output signal is proportional to the amount of fuel in the tank and the position of the float arm. The measured resistance is processed by the instrument cluster to implement an anti-slosh function. This monitors the signal and updates the fuel gauge pointer position at regular intervals, preventing constant pointer movement caused by fuel movement in the tank due to cornering or braking.

A warning lamp is incorporated in the instrument cluster and illuminates when the fuel level is low.

The fuel level sender signal is converted into a CAN (controller area network) message by the instrument cluster as a direct interpretation of

the fuel tank contents in liters.

LOW FUEL LEVEL SWITCH

E94666

ItemDescription

- | | |
|---|-----------------------|
| 1 | Low fuel level switch |
| 2 | Fuel pump module |

A fuel run-dry strategy has been programmed into the [ECM](#) software to prevent the fuel tank emptying completely. This strategy prevents damage to the fuel tank pump and the necessity of priming the fuel system.

In the event that the fuel is allowed to run too low, signals transmitted from a low-level switch, located in the swirl-pot of the fuel pump module, and both fuel level sensors initiate the fuel run-dry strategy.

Due to the location of the low-level switch there will only be a small amount of fuel left in the tank when the fuel run-dry strategy initiates. The driver will have been notified much earlier that the vehicle was low on fuel.

Although this is a simulated run-dry procedure, it provides the symptoms of the vehicle running out of fuel and the driver will perceive it as such. The engine will stop when there is approximately 4-liters of fuel remaining in the fuel tank.

JET PUMP

The fuel system incorporates a single jet pump in the [LH](#) side of the tank. The jet pump is located on the [LH](#) fuel level sensor carrier. The jet pump operates on a venturi effect created by the fuel at pump output pressure passing through the jet pump. This draws additional fuel from the tank through ports in the jet pump body.

The prime function of the jet pump is to collect fuel from the [LH](#) side of the tank and transfer it into the fuel pump module swirl pot on the [RH](#) side of the tank. The jet pump feature also serves to maintain an equal fuel level in the fuel tank compartments.

ROLL OVER VALVE

The ROV (roll over valve) is located in the upper half of the fuel tank and is connected via a pipe to the fuel level vent valve. The ROV (roll over valve) contains a non-return valve which closes in the event of the vehicle overturning, preventing liquid fuel escaping from the tank via the breather pipe.

FUEL LEVEL VENT VALVE

The fuel level vent valve is located in the upper half of the tank and is connected via pipework to the ROV (roll over valve) and the tank breather filter. The main purpose of the fuel level vent valve is to control the fill volume of the tank. During filling air, trapped inside the tank and a small amount of vapor is passed via the fuel level vent valve to the tank breather filter. The air and vapor mix then vents to atmosphere through the breather filter. During filling, when the tank reaches its full level, the fuel level vent valve closes and prevents air/vapor passing through to the tank breather filter. The resulting back pressure causes refueling to stop automatically.

Any further rise in air pressure is vented to the tank breather filter via the ROV (roll over valve).

The fuel level vent valve is always open when the fuel tank is below full, providing an unrestricted air/vapor outlet to the tank breather filter.

If a malfunction occurs in the fuel tank delivery system and the tank overfills, an integral pressure relief valve in the fuel level vent valve opens to provide a direct vent to the atmosphere.

FUEL FILTER

E94667

ItemDescription

1	Fuel damper
2	Fuel supply from fuel tank and under vehicle cooler
3	Air bleed to fuel tank
4	Fuel return to under vehicle cooler
5	Fuel diverter pipe
6	Fuel return from engine
7	Fuel feed to common-rail fuel pump

The fuel filter is a disposable canister type.

To prevent diesel waxing in cold conditions and to aid warm-up, a temperature sensitive regulating valve incorporated in the fuel filter housing, diverts a portion of the warm fuel returning from the engine into the fuel filter.

The regulating valve commences closing at 30 C (86°F) and fully closes at 50 C (122°F). When the valve is closed the returning fuel is diverted to the fuel filter via the under vehicle fuel cooler to maintain an optimum fuel temperature.

The filter has an air bleed return to the fuel tank which returns excess air and fuel to the tank.

The filter canister incorporates a chamber for collecting moisture. The moisture contained in the diesel fuel collects on the internal filter element and forms droplets, which fall into the moisture chamber. A drain plug located on the bottom of the filter canister is used to discharge the water.

FUEL FILLER PIPE ASSEMBLY

E94668

ItemDescription

1	Wide bore filler neck
2	Filler cap and tether
3	Fuel filler pipe

The aluminum filler neck has a wide bore neck specially designed to reduce diesel frothing while the fuel tank is being replenished.

FUEL COOLER

E94669

ItemDescription

- 1 Fuel cooler (low pressure side – under vehicle)
- 2 Fuel return to under vehicle cooler
- 3 Fuel return from engine

The low-pressure-side fuel cooler is situated under the vehicle, below the LH (left hand) front seat. The cooler is fuel to air cooled. Fuel flow through the underfloor cooler is controlled by the fuel filter.

Fuel Tank and Lines - TDV6 2.7L Diesel - Fuel Tank and Lines

Diagnosis and Testing

Principles of Operation

For a detailed description of the fuel tank and lines systems, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (310-01A Fuel Tank and Lines - TDV6 2.7L Diesel)

[Fuel Tank and Lines](#) (Description and Operation),
[Fuel Tank and Lines](#) (Description and Operation),
[Fuel Tank and Lines](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. Verify the customer concern.
2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> Fuel leaks Damaged fuel lines Damaged push connect fittings Fuel level Fuel contamination/grade/quality Damaged fuel tank filler pipe cap Damaged fuel tank filler pipe 	<ul style="list-style-type: none"> Fuses Loose or corroded electrical connectors Harnesses Fuel Pump Driver Module (FPDM) Central Junction Box (CJB) Fuel pump relay Engine Control Module (ECM)

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Engine cranks, but does not fire	<ul style="list-style-type: none"> Low/contaminated fuel Intake air leakage Fuel system leak, blocked/restricted Electronic engine controls 	Check for low/contaminated fuel. 		Diesel, Diagnosis and Testing).

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• **NOTE:** If a module or component is suspect, and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• **NOTE:** Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• **NOTE:** When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• **NOTE:** Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• **NOTE:** If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
P000113	Fuel Volume Regulator Control Circuit/Open	<ul style="list-style-type: none"> Fuel volume regulator control circuit - open circuit Fuel volume regulator control valve failure 	Refer to the electrical circuit diagrams and check fuel volume regulator control circuit for open circuit. Fuel Tank and Lines - V6 3.0L Petrol - Fuel Tank and Lines - Overview

Description and Operation

Authoring Template

OVERVIEW

The fuel system uses an electronic returnless system. The system comprises a pump module mounted in the fuel tank to deliver fuel at variable flow and pressure to the fuel rails which in turn supply fuel to the fuel injectors. The fuel pump operation is regulated by a [FPDM \(fuel pump driver module\)](#) which is controlled by the [ECM \(engine control module\)](#). The [FPDM](#) regulates the flow and pressure supplied by controlling the operation of the fuel pump using a [PWM \(pulse width modulation\)](#) output.

Two fuel level sensors are installed in either side of the saddle tank. The sensors are a MAPPS (magnetic passive position sensor) which provide a variable resistance to ground for the output from the fuel gauge.

The fuel system also incorporates an [EVAP \(evaporative emission\)](#) system which is part of the on-board refueling and vapor recovery feature. The function and operation of the system is designed to meet evaporative emission requirements to minimize fuel vapor losses. For additional information, refer to:

- Evaporative Emissions (303-13B, Description and Operation),
- Fuel Charging and Controls (303-04D, Description and Operation),
- Electronic Engine Controls (303-14C, Description and Operation).

15	Fuel injector

System Operation

The fuel pump is a variable-speed rotary-vane type, which operates in a fuel module located in the right hand fuel tank compartment. A fuel transfer pump is located in the left hand compartment. Both components are secured by screw on plastic closure rings. The fuel pump module has an integral top plate for the external pipe work and electrical connectors.

Fuel level is maintained equally in the fuel tank compartments by circulating the fuel through internal crossover pipes via suction jet pumps which also serve to deliver a constant supply of fuel to the transfer pump and swirl pot assembly. High pressure fuel from the fuel pump is directed through the jet pump's orifice, creating a low pressure area to be formed around the orifice. The fuel is drawn into this low pressure area and directed into the swirl pot delivery pipes. This is achieved using the cross-over pipe from the left hand module and a direct link pipe from the right hand module.

Fuel is pumped from the fuel pump to the fuel rail via the parallel pressure relief valve and fuel filter. The parallel pressure relief valve contains two spring loaded valves, which operate in opposite directions.

The pressure relief valve assists engine starting by retaining a pre-set fuel pressure in the supply pipe and fuel rail. The fuel pressure valve also limits fuel rail pressure due to temporary vapor increase in hot conditions and pressure caused by sudden load changes, for example, a fully open to closed throttle transition. In the event of the fuel delivery pipe being severed, the fuel pressure relief valve will prevent leakage from the fuel tank.

To meet **ORVR (on-board refueling vapor recovery)** requirements, the fuel tank and associated components are designed to minimize fuel vapor loss during refueling. This is achieved by preventing fuel vapor from the fuel tank venting directly to the atmosphere. Instead fuel vapor is directed into the **EVAP (evaporative emission)** canister where it is stored before being purged at intervals to the engine's intake

Component Description

FUEL TANK

E94484

ItemDescription

1	Charcoal canister
2	EVAP hose
3	Vapor pressure control valve
4	Fuel vapor valve

10	LH fuel level sensor float
11	Internal fuel transfer pipes
12	RH fuel level sensor float
13	Fuel pump module
14	RH fine mesh filter pick up
15	Fuel pump electrical connection

The fuel tank is a saddle type tank constructed of HDPE (high density polyethylene), a plastic blow molded material. The tank is located forward of the rear suspension and is mounted using two metal straps. The tank is a sealed unit with the only internal access being through the fuel pump module and transfer pump module flange apertures on the top of the tank.

The fuel pump module flange has a six pin external connector which provides the electrical connections for the fuel pump and level sensors. A quick release connector provides for the connection of the fuel feed pipe.

Each flange is fitted with a collar, clamp and seal which locate in the tank apertures. An arrow on each flange must be aligned between two molded lines on the tank, adjacent to the fuel pump module or transfer pump flange aperture, to obtain the correct pump orientation. A collar is located over each flange and is secured with a clamp. The flange, seal, collar and clamp arrangements meet the sealing requirements of LEV2 emissions.

FUEL PUMP MODULE

E74571

ItemDescription

1	Electrical connector
2	Fuel pump module
3	Fuel level sensor
4	Level sensor float

The fuel pump is a variable speed rotary vane type. The pump is energized by the fuel pump relay which is located in the [RJB \(rear junction box\)](#) and the [FPDM \(fuel pump driver module\)](#) which is located under the [RH](#) floor pan above the rear suspension stabilizer bar. The relay and [FPDM](#) are controlled by the [ECM \(engine control module\)](#).

A fine mesh filter is located in the lower section of the pump module. This provides filtration to the fuel as it is drawn into the module.

The right hand fuel level sensor is mounted into the pump module housing.

FUEL LEVEL SENSORS

E94420

ItemDescription

1	Fuel level sensor
2	Transfer pump module
3	Sensor mounting bracket
4	Fuel cross-over pipes
5	Fuel level sensor float
6	Fine mesh filter
7	Jet pump

Two fuel level sensors are installed in either side of the saddle tank. One is mounted on the fuel pump module, the other is mounted on the transfer pump module in the other side of the fuel tank. The sensors are a MAPPS (magnetic passive position sensor) which provide a variable resistance to ground for the output from the fuel gage. The sensor is sealed from the fuel preventing contamination of the contacts, increasing reliability. The fuel level sensors are connected to the external electrical connector on the flange via the connector on the underside of the fuel pump module flange.

The sensor comprises a series of 51 film resistors mounted in an arc on a ceramic surface. The resistors are wired in series with individual contacts. A soft magnetic foil with 51 flexible contacts is mounted a small distance above the film resistors. A magnet, located below the ceramic surface, is attached to the sender unit float arm. As the float arm moves, the magnet follows the same arc as the film resistors. The magnet pulls the flexible contacts onto the opposite film resistor contacts forming an electrical circuit.

MAPP Sensor Operating Principle

E44504

ItemDescription

1	Magnetic foil
2	Spacer
3	Ceramic surface
4	Magnet
5	Resistance film

The film resistors are arranged in a linear arc with resistance ranging from 51.2 to 992.11 Ohms. The electrical output signal is proportional to the amount of fuel in the tank and the position of the float arm. The measured resistance is processed by the instrument cluster to implement an anti-slosh function. This monitors the signal and updates the fuel gage pointer position at regular intervals, preventing constant pointer movement caused by fuel movement in the tank due to cornering or braking.

A warning lamp is incorporated in the instrument cluster and illuminates when the fuel level is low.

The fuel level sender signal is converted into a [CAN \(controller area network\)](#) message by the instrument cluster as a direct interpretation of the fuel tank contents in liters. The [ECM](#) uses the [CAN](#) message to store additional [OBD \(on-board diagnostic\)](#) 'P' Codes for misfire detection when the fuel level is below a predetermined capacity.

JET PUMPS

The fuel system incorporates two jet pumps. The [LH](#) jet pump is located on the fuel level sensor carrier on the [LH](#) side of the fuel tank. The [RH](#) jet pump is located in the swirl pot below the fuel pump. Both jet pumps operate on a venturi effect created by the fuel at pump output pressure passing through the jet pump. This draws additional fuel from the tank through ports in the jet pump body, delivering additional fuel to the swirl pot. This function also serves to maintain an equal fuel level in the fuel tank compartments.

The [LH](#) jet pump collects fuel from the [LH](#) side of the tank and transfers it into the swirl pot on the [RH](#) side of the tank.

The [RH](#) jet pump collects fuel from below the swirl pot and transfers it to the upper section of the swirl pot. The action of the jet pumps ensures a constant supply of fuel to the swirl pot and fuel pump. Both jet pumps have a jet nozzle of 0.5 mm diameter.

FUEL FILTER

The fuel filter is of a conventional construction being that of a paper element sealed within a steel canister. The fuel filter is located behind the left-hand front fender splash shield.

FUEL FILLER PIPE ASSEMBLY

E94485

ItemDescription

1	Fuel filler pipe
2	Filler cap and tether
3	Charcoal canister
4	EVAP pipe work

The fuel filler head is positioned at the rear of the vehicle, above the right hand rear wheel. The filler head is covered by a molded plastic cover which is electrically locked when the vehicle is locked. The filler cap is a conventional screw in type which is secured to the vehicle with a tether.

The filler head is an aluminum fabrication which is secured to the vehicle body by a bracket. The formed aluminum filler pipe locates in a short flexible hose attached to the tank which is secured with worm drive clamps.

Fuel Tank and Lines - V6 3.0L Petrol - Fuel Tank and Lines

Diagnosis and Testing

Principle of Operation

For a detailed description of the fuel tank and lines, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

- [Fuel Tank and Lines](#) (310-01B Fuel Tank and Lines - V6 3.0L Petrol, Description and Operation),
- [Fuel Tank and Lines](#) (310-01B Fuel Tank and Lines - V6 3.0L Petrol, Description and Operation),
- [Fuel Tank and Lines](#) (310-01B Fuel Tank and Lines - V6 3.0L Petrol, Description and Operation),
- [Fuel Tank and Lines](#) (310-01C Fuel Tank and Lines - V8 4.2L Petrol/V8 S/C 4.2L Petrol, Description and Operation),
- [Fuel Tank and Lines](#) (310-01C Fuel Tank and Lines - V8 4.2L Petrol/V8 S/C 4.2L Petrol, Description and Operation),
- [Fuel Tank and Lines](#) (310-01C Fuel Tank and Lines - V8 4.2L Petrol/V8 S/C 4.2L Petrol, Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Fuel leaks ● Damaged fuel lines ● Damaged push connect fittings ● Fuel level ● Fuel contamination/grade/quality ● Damaged fuel tank filler pipe cap ● Damaged fuel tank filler pipe 	<ul style="list-style-type: none"> ● Fuses ● Loose or corroded electrical connectors ● Harnesses ● Fuel Pump Driver Module (FPDM) ● Rear Junction Box (RJB) ● Fuel pump relay ● Engine Control Module (ECM)

3. 3. If an obvious cause for an observed or reported symptom is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) and proceed to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Engine cranks, but does not fire	<ul style="list-style-type: none"> ● Engine breather system disconnected/restricted ● Ignition system ● Fuel system ● Electronic engine controls 	Ensure the engine breather system is free from restriction and is correctly installed. DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: If a module or component is suspect, and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action

Fuel Tank and Lines - V6 3.0L Petrol - Fuel Filter

Removal and Installation

Removal

WARNING: Refer to: [Petrol and Petrol-Ethanol Fuel Systems Health and Safety Precautions](#) (100-00 General Information, Description and Operation).

• NOTE: Removal steps in this procedure may contain installation details.

1. De-pressurize the fuel system.

Refer to: [Fuel System Pressure Release - V8 4.2L Petrol/V8 S/C 4.2L Petrol/V6 3.0L Petrol](#) (310-00 Fuel System - General Information, General Procedures).

2. **WARNING:** Make sure to support the vehicle with axle stands.
Raise and support the vehicle.

3.

4. **CAUTION:** Make sure that all openings are sealed. Use new blanking caps.

5.

6. **6.** NOTE: Note the fitted position.

• WARNINGS:

-  Place the vehicle in a quarantined area and arrange "No Smoking/Petrol Fumes" signs about the vehicle.
-  Before any work is carried out on the fuel system, ground the vehicle to earth and maintain the ground connection until the work is complete.
-  Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.
-  The fuel system remains pressurized for a long time after the ignition is switched off. The fuel pressure must be relieved before attempting any repairs. Failure to follow these instructions may result in personal injury.
-  After carrying out repairs, the fuel system must be checked visually for leaks. Failure to follow these instructions may result in personal injury.
-  This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.
-  If taken internally, do not induce vomiting, seek immediate medical attention. Failure to follow these instructions may result in personal injury.
-  If fuel contacts the eyes, flush the eyes with cold water or eyewash solution and seek immediate medical attention.
-  Wash hands thoroughly after fuel handling, as prolonged contact may cause irritation. Should irritation develop, seek medical attention.

1. Raise and support the vehicle.
2. **NOTE:** All vehicles.
Open the fuel tank filler pipe flap.
3. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
4. Detach the fuel tank filler pipe cap.
5. Release the pressure in the fuel system.
For additional information, refer to: [Fuel System Pressure Release - V8 4.2L Petrol/V8 S/C 4.2L Petrol/V6 3.0L Petrol](#) (310-00 Fuel System - General Information, General Procedures).
6. Drain the fuel system.
For additional information, refer to: [Fuel Tank Draining](#) (310-00 Fuel System - General Information, General Procedures).
7. Detach and reposition the door opening weatherstrip.

VUJ0003895

8. Remove the scuff plate trim panel.

9. Detach and reposition the floor covering.

10. Detach and reposition the rear seat cushion insulation.

11. Remove the floor aperture cover.

12. Disconnect the fuel pump module electrical connector.

- Detach the fuel pump module wiring harness from the retaining bracket.

13. Disconnect the fuel pump module quick release coupling.

E63232

14. Using the special tool, remove the fuel pump module locking ring.

- Remove and discard the O-ring seal.

Removal and Installation

Removal

• WARNINGS:

 Before any work is carried out on the vehicle the fuel tank must have less than a 1/4 of a tank of fuel. This will prevent excessive fuel loss.

 Place the vehicle in a well ventilated, quarantined area and arrange 'No Smoking/Petrol Fumes' signs about the vehicle.

 Before any work is carried out on the fuel system, ground the vehicle to earth and maintain the ground connection until the work is complete.

 Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

 The fuel system remains pressurized for a long time after the ignition is switched off. The fuel pressure must be relieved before attempting any repairs. Failure to follow these instructions may result in personal injury.

 After carrying out repairs, the fuel system must be checked visually for leaks. Failure to follow these instructions may result in personal injury.

 This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

 If taken internally, do not induce vomiting, seek immediate medical attention. Failure to follow these instructions may result in personal injury.

 If fuel contacts the eyes, flush the eyes with cold water or eyewash solution and seek immediate medical attention.

 Wash hands thoroughly after fuel handling, as prolonged contact may cause irritation. Should irritation develop, seek medical attention.

1. Raise and support the vehicle.
2. Remove the fuel tank filler pipe cap.
3. Remove the right-hand rear wheel and tire.
For additional information, refer to: [Wheel and Tire](#) (204-04 Wheels and Tires, Removal and Installation).
4. Remove the right-hand rear fender splash shield.

5. Remove the fuel tank filler pipe retaining nut.

6. Remove the fuel tank filler pipe retaining nut.

Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Fuel Tank and Lines - Overview

Description and Operation

OVERVIEW

The fuel system uses an electronic returnless system. The system comprises a pump module mounted in the fuel tank to deliver fuel at variable flow and pressure to the fuel rails which in turn supply fuel to the fuel injectors. Fuel pump operation is regulated by a [FPDM \(fuel pump driver module\)](#) which is controlled by the [ECM \(engine control module\)](#). The [FPDM](#) regulates the flow and pressure supplied by controlling the operation of the fuel pump using a [PWM \(pulse width modulation\)](#) output.

Two fuel level sensors are installed in either side of the saddle tank. The sensors are a MAPPS (magnetic passive position sensor) which provide a variable resistance to ground for the output from the fuel gauge.

The fuel system also incorporates an [EVAP \(evaporative emission\)](#) system which is part of the on-board refueling and vapor recovery feature. The function and operation of the system is designed to meet [EVAP](#) requirements to minimize fuel vapor losses.

System Operation

System Operation

The fuel pump is a variable-speed rotary-vane type, which operates in a fuel module located in the right hand fuel tank compartment. A fuel transfer pump is located in the left hand compartment. Both components are secured by screw on plastic closure rings. The fuel pump module has an integral top plate for the external pipe work and electrical connectors.

Fuel level is maintained equally in the fuel tank compartments by circulating the fuel through internal crossover pipes via suction jet pumps which also serve to deliver a constant supply of fuel to the transfer pump and swirl pot assembly. High pressure fuel from the fuel pump is directed through the jet pump's orifice, creating a low pressure area to be formed around the orifice. The fuel is drawn into this low pressure area and directed into the swirl pot delivery pipes. This is achieved using the cross-over pipe from the left hand module and a direct link pipe from the right hand module.

Fuel is pumped from the fuel pump to the fuel rail via the parallel pressure relief valve and fuel filter. The parallel pressure relief valve contains two spring loaded valves, which operate in opposite directions.

The function of the valve is to

- Assist engine starting by retaining a pre-set fuel pressure in the supply pipe and fuel rail
- Limit fuel rail pressure due to temporary vapor increase in hot conditions
- Limit fuel rail pressure caused by sudden load changes, for example, a fully open to closed throttle transition
- Prevent leakage from the tank in the event that the fuel delivery pipe is severed

To meet ORVR (on-board refueling vapor recovery) requirements, the fuel tank and associated components are designed to minimize fuel vapor loss during refueling. This is achieved by preventing fuel vapor from the fuel tank venting directly to the atmosphere. Instead fuel vapor is directed into the EVAP (evaporative emission) canister where it is stored before being purged at intervals to the engine's intake manifold.

Component Description

FUEL TANK

ItemDescription

1	Charcoal canister

16	RH fine mesh filter pick up
17	Fuel pump electrical connection

The fuel tank is a saddle type tank constructed of HDPE (high density polyethylene), a plastic blow molded material. The tank is located forward of the rear suspension and is mounted using two metal straps. The tank is a sealed unit with the

only internal access being through the fuel pump module and transfer pump module flange apertures on the top of the tank.

The fuel pump module flange has a six pin external connector which provides the electrical connections for the fuel pump and level sensors. A quick release connector provides for the connection of the fuel feed pipe.

Each flange is fitted with a collar, clamp and seal which locate in the tank apertures. An arrow on each flange must be aligned between two molded lines on the tank, adjacent to the fuel pump module or transfer pump flange aperture, to obtain the correct pump orientation. A collar is located over each flange and is secured with a clamp. The flange, seal, collar and clamp arrangements meet the sealing requirements of LEV2 emissions.

paragraph

FUEL PUMP MODULE

E74571

ItemDescription

1	Electrical connector
2	Fuel pump module
3	Fuel level sensor
4	Level sensor float

The fuel pump is a variable speed rotary vane type. The supercharged variant incorporates a high flow rate pump . The pump is energized by the fuel pump relay which is located in the [RJB \(rear junction box\)](#) and the [FPDM \(fuel pump driver module\)](#) which is located under the RH floor pan above the rear suspension stabilizer bar . The relay and [FPDM](#) are controlled by the [ECM \(engine control module\)](#).

A fine mesh filter is located in the lower section of the pump module. This provides filtration to the fuel as it is drawn into the module.

The right hand fuel level sensor is mounted into the pump module housing.

FUEL LEVEL SENSORS

E94420

ItemDescription

1	Fuel level sensor
2	Transfer pump module
3	Sensor mounting bracket
4	Fuel cross-over pipes
5	Fuel level sensor float
6	Fine mesh filter
7	Jet pump

Two fuel level sensors are installed in either side of the saddle tank. One is mounted on the fuel pump module, the other is mounted on the transfer pump module in the other side of the fuel tank. The sensors are a MAPPS (magnetic passive position sensor) which provide a variable resistance to ground for the output from the fuel gage. The sensor is sealed from the fuel preventing contamination of the contacts, increasing reliability. The fuel level sensors are connected to the external electrical connector on the flange via the connector on the underside of the fuel pump module flange.

The sensor comprises a series of 51 film resistors mounted in an arc on a ceramic surface. The resistors are wired in series with individual contacts. A soft magnetic foil with 51 flexible contacts is mounted a small distance above the film resistors. A magnet, located below the ceramic surface, is attached to the sender unit float arm. As the float arm moves, the magnet follows the same arc as the film resistors. The magnet pulls the flexible contacts onto the opposite film resistor contacts forming an electrical circuit.

E44504

ItemDescription

1	Magnetic foil
2	Spacer
3	Ceramic surface

4 Magnet

5 Resistance film

The film resistors are arranged in a linear arc with resistance ranging from 51.2 to 992.11 Ohms. The electrical output signal is proportional to the amount of fuel in the tank and the position of the float arm. The measured resistance is processed by the instrument cluster to implement an anti-slosh function. This monitors the signal and updates the fuel gage pointer position at regular intervals, preventing constant pointer movement caused by fuel movement in the tank due to cornering or braking.

A warning lamp is incorporated in the instrument cluster and illuminates when the fuel level is low.

The fuel level sender signal is converted into a [CAN \(controller area network\)](#) message by the instrument cluster as a direct interpretation of the fuel tank contents in liters. The [ECM](#) uses the [CAN](#) message to store additional [OBD \(on-board diagnostic\)](#) 'P' Codes for misfire detection when the fuel level is below a predetermined capacity.

JET PUMPS

The fuel system incorporates two jet pumps. The LH (left hand) jet pump is located on the fuel level sensor carrier on the LH (left hand) side of the fuel tank. The RH jet pump is located in the swirl pot below the fuel pump. Both jet pumps operate on a venturi effect created by the fuel at pump output pressure passing through the jet pump. This draws additional fuel from the tank through ports in the jet pump body, delivering additional fuel to the swirl pot. This function also serves to maintain an equal fuel level in the fuel tank compartments.

The LH (left hand) jet pump collects fuel from the LH (left hand) side of the tank and transfers it into the swirl pot on the RH (right hand) side of the tank.

The RH (right hand) jet pump collects fuel from below the swirl pot and transfers it to the upper section of the swirl pot. The action of the jet pumps ensures a constant supply of fuel to the swirl pot and fuel pump. Both jet pumps have a jet nozzle of 0.5 mm diameter.

FUEL FILTER

The fuel filter is of a conventional construction being that of a paper element sealed within a steel canister. The fuel filter is located behind the left-hand front fender splash shield.

FUEL FILLER PIPE ASSEMBLY

E94421

ItemDescription

1	Filler cap and lanyard
2	EVAP pipe work
3	Charcoal canister
4	Fuel filler pipe
5	Filler cap and lanyard (NAS only)
6	Fuel filler pipe (NAS only) only

7	Fuel tank leakage monitoring pump (NAS only)
8	EVAP pipe work (NAS only)
9	Charcoal canister (NAS only)
10	Fuel tank leakage monitoring fresh air filter (NAS)

The fuel filler head is positioned at the rear of the vehicle, above the right hand rear wheel. The filler head is covered by a molded plastic cover which is electrically locked when the vehicle is locked. The filler cap is a conventional screw in type which is secured to the vehicle with a lanyard.

The filler head is an aluminum fabrication which is secured to the vehicle body by a bracket. The formed aluminum filler pipe locates in a short flexible hose attached to the tank which is secured with worm drive clamps.

NAS (North American Specification) vehicles feature connections and pipework on the rear of the filler head to allow for the functioning of the fuel tank [EVAP \(evaporative emission\)](#) system.

Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Fuel Tank and Lines

Diagnosis and Testing

Principle of Operation

For a detailed description of the fuel tank and lines, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (310-01 Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

[Fuel Tank and Lines](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Fuel leaks ● Damaged fuel lines ● Damaged push connect fittings ● Fuel level ● Fuel contamination/grade/quality ● Damaged fuel tank filler pipe cap ● Damaged fuel tank filler pipe 	<ul style="list-style-type: none"> ● Fuses ● Loose or corroded electrical connectors ● Harnesses ● Fuel Pump Driver Module (FPDM) ● Rear Junction Box (RJB) ● Fuel pump relay ● Engine Control Module (ECM)

3. 3. If an obvious cause for an observed or reported symptom is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart below, alternatively, check for Diagnostic Trouble Codes (DTCs) and proceed to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Engine cranks, but does not fire	<ul style="list-style-type: none"> ● Engine breather system disconnected/restricted ● Ignition system ● Fuel system ● Electronic engine controls 	Ensure the engine breather system is free from restriction and is correctly installed. DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• NOTE: If a module or component is suspect, and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Fuel Filter

Removal and Installation

Removal

 **WARNING:** Refer to: [Petrol and Petrol-Ethanol Fuel Systems Health and Safety Precautions](#) (100-00 General Information, Description and Operation).

• **NOTE:** Removal steps in this procedure may contain installation details.

1. De-pressurize the fuel system.

Refer to: [Fuel System Pressure Release - 3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8](#) (310-00 Fuel System - General Information, General Procedures).

2.  **WARNING:** Make sure to support the vehicle with axle stands.

Raise and support the vehicle.

- 3.

4.  **CAUTION:** Make sure that all openings are sealed. Use new blanking caps.

5.

6. **6.** NOTE: Note the fitted position.

Installation

1. To install, reverse the removal procedure.

Removal and Installation

Special Tool(s)	
	Remover/Installer, Fuel Pump Module/Fuel Transfer Unit Locking Ring 310-146

Removal

• WARNINGS:

Place the vehicle in a quarantined area and arrange "No Smoking/Petrol Fumes" signs about the vehicle.

Before any work is carried out on the fuel system, ground the vehicle to earth and maintain the ground connection until the work is complete.

Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.

The fuel system remains pressurized for a long time after the ignition is switched off. The fuel pressure must be relieved before attempting any repairs. Failure to follow these instructions may result in personal injury.

After carrying out repairs, the fuel system must be checked visually for leaks. Failure to follow these instructions may result in personal injury.

This procedure involves fuel handling. Be prepared for fuel spillage at all times and always observe fuel handling precautions. Failure to follow these instructions may result in personal injury.

If taken internally, do not induce vomiting, seek immediate medical attention. Failure to follow these instructions may result in personal injury.

If fuel contacts the eyes, flush the eyes with cold water or eyewash solution and seek immediate medical attention.

Wash hands thoroughly after fuel handling, as prolonged contact may cause irritation. Should irritation develop, seek medical attention.

1. Raise and support the vehicle.
2. NOTE: All vehicles.
Open the fuel tank filler pipe flap.
3. Disconnect the battery ground cable.
For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
4. Detach the fuel tank filler pipe cap.
5. Release the pressure in the fuel system.
For additional information, refer to: [Fuel System Pressure Release - 3.0L NA V6 - AJ27/4.2L NA V8 - AJV8/4.2L SC V8 - AJV8](#) (310-00 Fuel System - General Information, General Procedures).
6. Drain the fuel system.
For additional information, refer to: [Fuel Tank Draining](#) (310-00 Fuel System - General Information, General Procedures).

7. Detach and reposition the door opening weatherstrip.

8. Remove the scuff plate trim panel.

9. Detach and reposition the floor covering.

10. Detach and reposition the rear seat cushion insulation.

11. Remove the floor aperture cover.

12. Disconnect the fuel pump module electrical connector.

- Detach the fuel pump module wiring harness from the retaining bracket.

13. Disconnect the fuel pump module quick release coupling.

14. Using the special tool, remove the fuel pump module locking ring.

- Remove and discard the O-ring seal.

15. Disconnect the fuel transfer module transfer feed tube.

16. Disconnect the left-hand fuel sender gauge electrical connector.

17. Disconnect the fuel transfer module transfer return tube.

18.  CAUTION: Make sure no damage occurs to the fuel level float.

Remove the fuel pump module.

- Press down and rotate the base of the fuel pump module counter-clockwise.

Installation

1. CAUTIONS:

- ⚠ On vehicles with supercharger make sure the arrow on the fuel pump module and the 'SC' marker on the fuel tank are aligned.
- ⚠ On vehicles without supercharger make sure the arrow on the fuel transfer module and the 'NA' marker on the fuel tank are aligned.
- ⚠ Make sure no damage occurs to the fuel level float.

• NOTE: All vehicles.

Install the fuel pump module.

- Press down and rotate the base of the fuel pump module clockwise.

2. Connect the transfer module transfer return tube.

- Make sure the coupling has latched onto the fuel pump module by pulling the tube after the connection has been made.

3. Connect the left-hand fuel sender gauge electrical connector.

4. Connect the fuel transfer module transfer feed tube.

- Make sure the quick release coupling has latched onto the fuel pump module fuel tube by pulling the tube after the connection has been made.

E63233

5. Using the special tool, install the fuel pump module locking ring.

- Install a new O-ring seal.
- Tighten to 60 Nm.

E63232

6. Connect the fuel pump module quick release coupling.

- Make sure the quick release coupling has latched onto the fuel pump module fuel pipe by pulling the pipe after the connection has been made.

E63231

7. Connect the fuel pump module electrical connector.

- Attach the fuel pump module wiring harness to the retaining bracket.

VUJ0003899

8. Install the floor aperture cover.

9. Attach the rear seat cushion insulation.

10. Attach the floor covering.

11. Install the scuff plate trim panel.

12. Attach the door opening weatherstrip.

13. Attach the fuel tank filler pipe cap.

14. Connect the battery ground cable.

For additional information, refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

15. Close the fuel tank filler pipe flap.

Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Fuel Tank

Removal and Installation

Removal

- NOTE: Removal steps in this procedure may contain installation details.

All vehicles

1. Refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).
2. Refer to: [Fuel Tank Draining](#) (310-00 Fuel System - General Information, General Procedures).

3.  **WARNING:** Do not work on or under a vehicle supported only by a jack. Always support the vehicle on safety stands.

Raise and support the vehicle.

4. Refer to: [Driveshaft](#) (205-01 Driveshaft, Removal and Installation).

5.
 - Torque: 5 Nm

6.  **WARNING:** The spilling of fuel is unavoidable during this operation. Make sure that all necessary precautions are taken to prevent fire and explosion.

Vehicles with petrol engine

7.

All vehicles

8.

- Torque: 3 Nm

9.  **WARNING:** Secure the component to the transmission jack.

 **CAUTION:** Use suitable packing material to prevent damage to the component.

- Torque: 35 Nm

Installation

1. To install, reverse the removal procedure.

Fuel Tank and Lines - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Fuel Tank Filler Pipe

Removal and Installation

Removal

• WARNINGS:

-  Before any work is carried out on the vehicle the fuel tank must have less than a 1/4 of a tank of fuel. This will prevent excessive fuel loss.
-  Place the vehicle in a well ventilated, quarantined area and arrange ' No Smoking/Petrol Fumes' signs about the vehicle.
-  Before any work is carried out on the fuel system, ground the vehicle to earth and maintain the ground connection until the work is complete.
-  Do not smoke or carry lighted tobacco or open flame of any type when working on or near any fuel related components. Highly flammable vapors are always present and may ignite. Failure to follow these instructions may result in personal injury.
-  The fuel system remains pressurized for a long time after the ignition is switched off. The fuel pressure must be relieved before attempting any repairs. Failure to follow these instructions may result in personal injury.

Acceleration Control -

Torque Specifications

Description	Nm	lb-ft	lb-in
Accelerator pedal	10	7	89

Acceleration Control - Acceleration Control

Diagnosis and Testing

Principles of Operation

For a detailed description of the acceleration controls, refer to the relevant Description and Operation sections in the workshop manual. REFER to: Acceleration Control (310-02, Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Accelerator pedal ● Throttle body 	<ul style="list-style-type: none"> ● Fuses ● Wiring harness ● Electrical connector(s) ● Sensor(s) ● Engine control module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• **NOTE:** If the module or a component is suspect and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• **NOTE:** Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).

• **NOTE:** When performing electrical voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• **NOTE:** Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• **NOTE:** If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action

Speed Control - TDV6 2.7L Diesel - Speed Control - Overview

Description and Operation

Overview

There are two variants of speed control available, a standard system and an adaptive system. The standard system maintains a set speed selected by the driver until operation is suspended or cancelled by a further input from the driver and is controlled by the [ECM \(engine control module\)](#)ECM. The adaptive system includes the same functionality as the standard system, but also has the ability to:

- Reduce vehicle speed, to less than the set speed, in order to maintain a selected distance behind a slower moving vehicle
- Accelerate the vehicle back to the set speed, once the way ahead is clear, after reducing the set speed because of a slower moving vehicle
- Alert the driver when the vehicle comes within a given distance of a slower moving vehicle

The standard system and the adaptive system both have the following components:

- A set +/- switch
- A RESUME switch
- A CANCEL switch

Both systems also use:

- The [ECM](#)
- The brake switch.
- The [APP \(accelerator pedal position\)](#) sensor.

The adaptive system incorporates the following additional components:

- An adaptive speed control module
- An adaptive speed control sensor
- A forward alert switch
- The [ABS \(anti-lock brake system\)](#) control module

13	TCM (transmission control module)
14	Adaptive speed control module

System Operation

Overview

The speed control system is integrated with the engine management system and uses Fueling intervention to automatically maintain a set vehicle speed. Once engaged, the system can also be used to accelerate the vehicle without using the accelerator pedal. The speed control system comprises the following components:

- '+' and '-' (set/accelerate and decelerate) steering wheel switches
- Resume switch
- Clock spring
- Speed control warning lamp.

The speed control system also uses inputs from the brake pedal switch, the [APP](#) sensor, the [ECM](#) and the [ABS](#) control module.

The speed control is operated by the driver using only the steering wheel switches. When speed control is active, the [ECM](#) regulates the [PWM \(pulse width modulation\)](#) signals to the fuel injectors to adjust the fuel supply as required to maintain the set speed.

During speed control operation, the [ECM](#) controls vehicle speed by adjusting fuel injection duration and timing. When the accelerator pedal is pressed with speed control active, the [ECM](#) outputs a calculated throttle angle signal in place of the actual throttle angle signals produced by the [APP](#) sensor. The calculated throttle angle is derived from fuel demand.

The minimum set speed for speed control is 20 mph (32 (km/h)). Speed control is automatically suspended if the following conditions apply:

- Vehicle speed falls below 16 mph (26 km/h).
- The brake pedal is pressed.
- The cancel button is pressed.
- Neutral, park or reverse gear is selected.
- The difference between actual speed and the set speed is too great.
- When the vehicle speed reaches a maximum speed of 150 mph (240 kph).
- If the accelerator pedal is used to accelerate beyond the set speed for too long.

Adaptive Speed Control

The adaptive speed control system comprises the following components:

- Adaptive Speed Control Sensor
- Adaptive Speed Control module
- Steering wheel control switches
- [ECM](#)
- Electric throttle
- [ABS](#) module and pump
- Adaptive Speed Control warning lamp (in the instrument cluster)

The adaptive speed control system uses a forward looking radar sensor to scan the road ahead, looking for objects that are moving at a different rate to itself. When a target is identified the adaptive speed control system will monitor the time gap between it and the target vehicle. When that gap falls below a set driver selected level the adaptive speed control system will intervene slowing the vehicle by backing off the throttle and/ or applying the brakes, until the correct gap is attained. The driver can chose between four gap settings, 1, 1.4, 1.8 and 2.2 seconds.

The system will detect but not react to the following:

- Vehicles in the oncoming lane
- Stationary vehicles
- Pedestrians
- Vehicles not in the same lane

Adaptive speed control is active when the vehicle is moving. Adaptive Speed Control only functions when a set speed is entered in normal speed control mode. The adaptive speed control system only intervenes with the set speed when it detects a target vehicle, and then only if the minimum time gap is breached.

It is important to note that the system is intended for use in limited driving situations, does not remove control and responsibility from the driver, and at all times can be quickly overridden. The adaptive speed control system is not a collision warning system and will not react to stationary objects. The system does not operate below a minimum speed of approximately 16 mph (26 km/h) since it is unsuitable for use in cities or congested traffic. The system is best suited to main roads/ highways with gradual bends.

The [ECM](#), throttle body and throttle control are unchanged from those used for non Adaptive Speed Control variants.

The adaptive speed control system is based on the use of a front mounted radar sensor. The sensor transmits a 1.5° wide beam forward of the vehicle and detects the returning signals reflected off other vehicles and objects ahead.

The 1.5° wide radar beam is mechanically scanned at a rate of 10 sweeps/second across a total arc of 15° centered on the longitudinal axis of the vehicle. The radar operates at millimetric wavelengths (76 - 77 GHz) and transmits a frequency modulated continuous wave signal at a relatively low power level (no high power pulses).

With the ignition switched ON, the adaptive speed control module is powered up but no radar transmissions are emitted until the vehicle is in motion.

In follow mode a set speed is selected in the normal speed control manner and this speed is maintained until a slower vehicle is encountered in the lane ahead. When the vehicle ahead comes within the effective range of the radar sensor, the system identifies it as a target vehicle and an icon is illuminated on the instrument cluster to indicate that the system is in "follow mode". When the distance between the two vehicles closes to a set time gap, the adaptive speed control system closes the throttle and if necessary applies the brakes to maintain the set time gap. Follow mode is effectively a closed loop system. If several vehicles are ahead, the closest vehicle is chosen as the target to follow. If the target vehicle moves out of radar range, or if either vehicle changes lane or drops below the minimum operating speed, the system exits follow mode and the follow mode icon is extinguished. The adaptive speed control system will only raise its speed to the originally set speed, it will not accelerate past this speed to maintain a time gap.

Driver operation of the foot brake or control switches will immediately cancel adaptive speed control.

When the vehicle is in follow mode the follow mode warning indicator is illuminated in the instrument cluster and the current gap setting will be displayed in the message center.

E98452

ItemDescription

- | | |
|---|---------------------------------|
| 1 | Forward Alert warning indicator |
| 2 | Follow mode warning indicator |

The radar sensor detects three primary parameters of objects within the scanned arc. These are:

- Range
- Relative velocity
- Angle

Range: The radar sensor detects the presence and ranges of different vehicles and objects within the scanned arc up to a distance of approximately 130 meters. The transmitted signal frequency changes continuously in a cyclic pattern (modulation). This means that, in the time taken for the signal wave front, to travel to and from a target vehicle (or other object), the transmission frequency will have changed. The difference between the received signal frequency and the new transmission frequency is proportional to the distance between the transmitting vehicle and the target vehicle.

Relative velocity: When the signal is reflected off a vehicle moving at a different speed (opening or closing gap) an effect known as the Doppler shift causes an extra frequency modulation to be imposed on the signal. This Doppler frequency varies with the relative speed of the vehicle being followed, enabling the system to differentiate between vehicles traveling at different speeds and also between moving vehicles and stationary objects.

Angle: Using a narrow angle beam to scan horizontally enables the system to distinguish between vehicles in different lanes and between vehicles and roadside objects.

System Restrictions

The adaptive speed control system is only intended to provide enhanced speed control as described above in certain restricted conditions. The following points should be noted:

- Automatic braking is limited to approximately 30% of full pressure (0.3G deceleration) and is intended to provide a smooth, gradual deceleration in follow mode conditions. Harsh braking by the target vehicle or following the target vehicle down to very low speeds or to a halt will require driver override of the brakes.
- While the radar sensor detects moving and stationary targets for assessment of the environment ahead, the system does not react to or provide any control in situations other than follow mode conditions. Stationary or slow moving vehicles (below 10 km/h), pedestrians, objects on the road and oncoming vehicles in the same lane are not recognized.

WARNING: It must be emphasized that the adaptive speed control system is not a collision warning or avoidance system and that, other than the limited conditions of follow mode, driver intervention will be necessary to control the vehicle speed.

In follow mode, some situations may cause target ambiguities for the detection system. These situations include:

- The nearby presence of a third vehicle when driving on a line slightly offset to the target vehicle.
- Vehicles edging into the lane ahead which are not detected by the system until they have moved into the radar beam.

On the approach to, or exit from a bend, a target vehicle may be lost or a new target acquired as vehicles ahead change their angular position with respect to the radar sensor. On a straight road, if the sensing vehicle is in follow mode below its selected set speed, losing the target vehicle will cause the sensing vehicle to accelerate to this set speed. This acceleration is undesirable either on, or entering a bend when the target is suddenly lost, and in this situation the system inhibits the resumption of the set speed.

The speed control system compares vehicle speed data from the [ABS](#) system with the relative speed of an external object as detected by the radar sensor to ascertain whether the object is stationary or not.

• **NOTE:** If tires are fitted which are different in diameter from those specified for the vehicle, the vehicle speed calculated by the [ABS](#) will not be the true road speed. This situation may cause stationary objects to be falsely identified as moving vehicles and result in automatic deceleration on a clear road.

Component Description

Speed Control Switches

E98448

ItemDescription

1	Set speed adjustment switch
2	Time gap switch
3	Cancel switch
4	Resume switch

The speed control switches are located on the RH (Right-hand) side of the steering wheel. The switches are connected via fly leads to the clock spring. The speed control switches are resistive ladder type switches which vary the resistance of a 5 volt signal sent to them. The signal is returned along a Lin bus to the instrument cluster. The instrument cluster routes the control signals to the [ECM](#) on the HS [CAN](#).

Speed control is engaged by rotating the speed adjustment switch to the + or - positions. Once engaged the speed can be varied by the speed adjustment switches. Each press of the speed adjustment switch will increase or decrease the set speed in steps of 1 mph (2 kph).

Adaptive Speed Control Module

E98450

The Adaptive Speed Control module, located on the drivers side at the bottom of the A post. The control module is connected to the other vehicle systems via the high speed [CAN](#) bus. Signals from the Adaptive Speed Control forward looking radar sensor are received on a dedicated [CAN](#) bus between the two modules.

Adaptive Speed Control Radar Sensor

E98451

The adaptive speed control radar sensor is located in the front bumper, on the **RH (right-hand)** side above the radiator grill behind the bumper cover. The sensor is connected to the Adaptive Speed Control, module via a private **CAN** bus. If the unit is replaced in service the unit must be re-aligned vertically. Horizontal alignment is achieved by putting the sensor in service mode via the recommended Jaguar diagnostic tool.

The vehicle is then driven for a short period while the sensor calibrates itself. Calibration is complete when the 'follow' icon in the instrument cluster stops flashing.

Forward Alert Switches

E98449

ItemDescription

1 Forward alert switch

The forward alert system utilizes the Adaptive Speed Control system components. Forward alert is turned on and off independently of Adaptive Speed Control, via a switch mounted in the lower outboard knee bolster switchpack. Forward alert will notify the driver by means of a chime, and warning indicator in the instrument cluster and indication in the message center, when a target vehicle comes into range. The system will NOT use throttle or brake intervention to slow the vehicle.

The forward alert switch is connected to the instrument cluster in a resistive ladder with the luggage compartment opening switch and the fuel filler flap switch. The instrument cluster sends the forward alert information to the Adaptive speed control module on the **CAN** bus.

• **NOTE:** This system is intended as a driver aid and should be used as such. The system is NOT a collision warning or avoidance device.

The system sensitivity can be adjusted in the same manner as the Adaptive Speed Control, via the steering wheel mounted switches. Each adjustment is accompanied by a message in the message center.

Speed Control - TDV6 2.7L Diesel - Speed Control

Diagnosis and Testing

Principles of Operation

For a detailed description of the speed control system, refer to the relevant Description and Operation sections in the workshop manual. REFER to:

- [Speed Control](#) (310-03A Speed Control - TDV6 2.7L Diesel, Description and Operation),
- [Speed Control](#) (310-03A Speed Control - TDV6 2.7L Diesel, Description and Operation),
- [Speed Control](#) (310-03A Speed Control - TDV6 2.7L Diesel, Description and Operation),
- [Speed Control](#) (310-03 Speed Control - 3.0L, Description and Operation),

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Speed control sensor ● Ensure the speed control sensor is free from obstructions ● Speed control module ● Brake switch 	<ul style="list-style-type: none"> ● Fuses ● Wiring harness ● Electrical connector(s) ● Steering wheel switches ● Brake switch ● Speed control sensor ● Speed control module ● Engine Control Module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Speed Control Sensor Adjustment (vehicles with adaptive system installed)

An incorrectly aligned speed control sensor can cause incorrect system operation. Before starting any repair work on the speed control system, on vehicles with the adaptive system installed, check speed control sensor for correct vertical alignment, and carry out speed control sensor alignment procedure using manufacturer approved diagnostic system.

DTC Index

Vehicles WITH Adaptive System Installed

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

- NOTE: If a module or component is suspect, and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).
- NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Vehicles WITHOUT Adaptive System Installed

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

- NOTE: If a module or component is suspect, and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).
- NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

6.

- Configure the ACC module using the diagnostic tool.
- This procedure is required if:
- A new ACC radar and, or ACC module are installed.
- The ACC radar needed to be removed or is misaligned in its position due to another repair operation.

7.

- From the diagnostic tool menu, select: Service Alignment Mode.
- The follow indicator will now be flashing, this indicates that the vehicle is in "service alignment" and now requires driving.
- The vehicle speed must be above 30mph (48 kph).
- Choose a road with plenty of stationary objects, like street lights, road signs, or barriers. Use an inside or outside lane.
- Following vehicles too closely will obscure the stationary targets from the radar, a time gap of 2 seconds is recommended.
- A straight road will produce a quicker and better result, although the process will still operate on a curved road.
- The time that the ACC module takes to align will vary, depending on the route, speed, number of targets, and individual module.
- When the flashing follow indicator light extinguishes, the ACC system is now functional, and a required vehicle speed can now be set by the driver and the ACC system will operate as normal.

Speed Control - V6 3.0L Petrol - Speed Control - Overview

Description and Operation

OVERVIEW

The speed control system maintains a set speed selected by the driver until operation is suspended or cancelled by a further input from the driver and is controlled by the [ECM \(engine control module\)](#).

The speed control system has the following components:

- A SET + switch
- A - switch
- A RESUME switch
- A CANCEL switch

The speed control system also uses:

- The [ECM](#)
- The stop lamp switch
- The [APP \(accelerator pedal position\)](#) sensor.

System Operation

SPEED CONTROL

The speed control system is integrated with the engine management system and uses fueling intervention to automatically maintain a set vehicle speed. Once engaged, the system can also be used to accelerate the vehicle without using the accelerator pedal. The speed control system comprises the following components:

- '+' and '-' (set/accelerate and decelerate) steering wheel switches
- Resume switch
- Cancel switch
- Clock spring
- Speed control warning indicator.

The speed control system also uses inputs from the brake pedal switch, the [APP](#) sensor, the [ECM](#) and the [ABS](#) module.

The speed control is operated by the driver using only the steering wheel switches. When speed control is active, the [ECM](#) regulates the [PWM \(pulse width modulation\)](#) signals to the fuel injectors to adjust the fuel supply as required to maintain the set speed.

During speed control operation, the [ECM](#) controls vehicle speed by adjusting fuel injection duration and timing. When the accelerator pedal is pressed with speed control active, the [ECM](#) outputs a calculated throttle angle signal in place of the actual throttle angle signals produced by the [APP](#) sensor. The calculated throttle angle is derived from fuel demand based on the torque required to overcome the rolling resistance (vehicle motion drag).

The minimum set speed for speed control is 20 mph (32 (km/h)). Speed control is automatically suspended if the following conditions apply:

- Vehicle speed falls below 20 mph (32 km/h).
- The brake pedal is pressed.
- The cancel button is pressed.
- Neutral, park or reverse gear is selected.
- The difference between actual speed and the set speed is too great.
- If the accelerator pedal is used to accelerate beyond the set speed for too long (more than 5 minutes).
- Stability control system intervention
- System error causes shut-off.

There are 4 standard speed control switches:

- Set speed + accelerate switch
- Decelerate - switch
- Cancel switch
- Resume switch.

The standard speed control switches are located on the [RH \(right-hand\)](#) side of the steering wheel. The switches are resistive ladder type switches which vary the resistance of a voltage signal sent to them. The resistive ladder is wired to a control module within the switch assembly, the control module is a [LIN \(local interconnect network\)](#) node which transmits the data to the [CJB \(central junction box\)](#) which passes the data onto the high speed [CAN](#) bus. In the event of the [ECM](#) logging a cruise switch fault [DTC \(diagnostic trouble code\)](#), fault finding should start at the switch assembly and clockspring. The [ECM](#) diagnostic detects that the switch assembly control module hasn't provided an updated live counter.

Engage Speed Control

Speed control is engaged by pressing the set speed accelerate + switch. Once engaged the speed can be increased by one of 3 methods:

- Press and hold the set speed accelerate + switch which will cause the vehicle to accelerate. When the switch is released the attained speed will be set as the cruise speed.
- Repeatedly pressing the set speed accelerate + switch. Each press increases the vehicle speed by 1 mph (2 km/h).
- Use the accelerator pedal to increase the vehicle speed. Once the required speed is reached, a single press of the set speed accelerate + switch will set the cruise speed.

Reduce Cruising Speed

The set speed can be reduced by pressing and holding the decelerate - switch until the required speed is reached. When the switch is released the speed is reset at that value. The set speed can be reduced incrementally by pressing and releasing the decelerate - switch. Each press will reduce the speed by 1 mph (2 km/h). Adaptive speed control braking can be induced by using the SET – switch to decelerate the vehicle.

Set Speed Adjustment

Speed control adjustment is limited around the current vehicle speed. This means speed adjustment won't occur when resuming or if the vehicle speed is noticeably different to set speed. This is noticeable when resuming speed control and a large difference exists between the set speed and the current speed. The driver can set a new speed, but can't adjust the old speed.

Suspend Speed control

Suspending speed control means speed control has been deactivated without loss of the memory speed. In all suspend events the memory speed is maintained. Speed control can be suspended in a number of ways, as described in the general description.

A single press of the RESUME switch will resume speed control at the previously set speed.

• **NOTE:** In the event that a memory speed has been lost during a driving cycle, confirm with the customer if the "Cruise Not Available" message was observed. Loss of memory speed implies a fault has occurred. The message 'Cruise Not Available' may only be displayed on demand for some errors, so speed control needs to be requested via the SET + switch to drive the message.

System Operation

Overview

The speed control system is integrated with the engine management system and uses Fueling intervention to automatically maintain a set vehicle speed. Once engaged, the system can also be used to accelerate the vehicle without using the accelerator pedal. The speed control system comprises the following components:

- On/Off/Suspend switch
- '+' and '-' (set/accelerate and decelerate) steering wheel switches
- Resume switch
- Clock spring
- Speed control warning lamp.

The speed control system also uses inputs from the brake pedal switch, the [APP](#) sensor, the [ECM](#) and the [ABS](#) control module.

The speed control is operated by the driver using only the steering wheel switches. When speed control is active, the [ECM](#) regulates the [PWM \(pulse width modulation\)](#) signals to the fuel injectors to adjust the fuel supply as required to maintain the set speed.

During speed control operation, the [ECM](#) controls vehicle speed by adjusting the electronic throttle. When the accelerator pedal is pressed with speed control active, the [ECM](#) outputs a calculated throttle angle signal in place of the actual throttle angle signals produced by the [APP](#) sensor. The calculated throttle angle is derived from fuel demand.

The minimum set speed for speed control is 18 mph (30 km/h). Speed control is automatically suspended if the following conditions apply:

- Vehicle speed falls below 18 mph (30 km/h).
- The brake pedal is pressed.
- The cancel button is pressed.
- Neutral, park or reverse gear is selected.
- The difference between actual speed and the set speed is too great.
- When the vehicle speed reaches a maximum speed of 120 mph (192 kph).
- If the accelerator pedal is used to accelerate beyond the set speed for too long.

Adaptive Speed Control

The adaptive speed control system comprises the following components:

- Adaptive Speed Control Sensor
- Adaptive Speed Control module
- Steering wheel control switches
- [ECM](#)
- Electric throttle
- [ABS](#) module and pump
- Adaptive Speed Control warning lamp (in the instrument cluster)

The adaptive speed control system uses a forward looking radar sensor to scan the road ahead, looking for objects that are moving at a different rate to itself. When a target is identified the adaptive speed control system will monitor the time gap between it and the target vehicle. When that gap falls below a set driver selected level the adaptive speed control system will intervene slowing the vehicle by backing off the throttle and/ or applying the brakes, until the correct gap is attained. The driver can chose between four gap settings, 1, 1.4, 1.8 and 2.2 seconds.

The system will detect but not react to the following:

- Vehicles in the oncoming lane
- Stationary vehicles
- Pedestrians
- Vehicles not in the same lane

Adaptive speed control is active when the vehicle is moving. Adaptive Speed Control only functions when a set speed is entered in normal speed control mode. The adaptive speed control system only intervenes with the set speed when it detects a target vehicle, and then only if the minimum time gap is breached.

It is important to note that the system is intended for use in limited driving situations, does not remove control and responsibility from the driver, and at all times can be quickly overridden. The adaptive speed control system is not a collision warning system and will not react to stationary objects. The system does not operate below a minimum speed of approximately 30 km/h (20 mph) since it is unsuitable for use in cities or congested traffic. The system is best suited to main roads/ highways with gradual bends.

The [ECM](#), throttle body and throttle control are unchanged from those used for non Adaptive Speed Control variants.

The adaptive speed control system is based on the use of a front mounted radar sensor. The sensor transmits a 1.5° wide beam forward of the vehicle and detects the returning signals reflected off other vehicles and objects ahead.

The 1.5° wide radar beam is mechanically scanned at a rate of 10 sweeps/second across a total arc of 15° centered on the longitudinal axis of the vehicle. The radar operates at millimetric wavelengths (76 - 77 GHz) and transmits a frequency modulated continuous wave signal at a relatively low power level (no high power pulses).

With the ignition switched ON, the adaptive speed control module is powered up but no radar transmissions are emitted until the vehicle is in motion.

In follow mode a set speed is selected in the normal speed control manner and this speed is maintained until a slower vehicle is encountered in the lane ahead. When the vehicle ahead comes within the effective range of the radar sensor, the system identifies it as a target vehicle and an icon is illuminated on the instrument cluster to indicate that the system is in "follow mode". When the distance between the two vehicles closes to a set time gap, the adaptive speed control system closes the throttle and if necessary applies the brakes to maintain the set time gap. Follow mode is effectively a closed loop system. If several vehicles are ahead, the closest vehicle is chosen as the target to follow. If the target vehicle moves out of radar range, or if either vehicle changes lane or drops below the minimum operating speed, the system exits follow mode and the follow mode icon is extinguished. The adaptive speed control system will only raise its speed to the originally set speed, it will not accelerate past this speed to maintain a time gap.

Driver operation of the foot brake or control switches will immediately cancel adaptive speed control.

When the vehicle is in follow mode the follow mode warning indicator is illuminated in the instrument cluster and the current gap setting will be displayed in the message center.

E98452

ItemDescription

1	Forward Alert warning indicator
2	Follow mode warning indicator

The radar sensor detects three primary parameters of objects within the scanned arc. These are:

- Range
- Relative velocity
- Angle

Range: The radar sensor detects the presence and ranges of different vehicles and objects within the scanned arc up to a distance of approximately 130 meters. The transmitted signal frequency changes continuously in a cyclic pattern (modulation). This means that, in the time taken for the signal wave front, to travel to and from a target vehicle (or other object), the transmission frequency will have changed. The difference between the received signal frequency and the new transmission frequency is proportional to the distance between the transmitting vehicle and the target vehicle.

Relative velocity: When the signal is reflected off a vehicle moving at a different speed (opening or closing gap) an effect known as the Doppler shift causes an extra frequency modulation to be imposed on the signal. This Doppler frequency varies with the relative speed of the vehicle being followed, enabling the system to differentiate between vehicles traveling at different speeds and also between moving vehicles and stationary objects.

Angle: Using a narrow angle beam to scan horizontally enables the system to distinguish between vehicles in different lanes and between vehicles and roadside objects.

System Restrictions

The adaptive speed control system is only intended to provide enhanced speed control as described above in certain restricted conditions. The following points should be noted:

- Automatic braking is limited to approximately 30% of full pressure (0.3G deceleration) and is intended to provide a smooth, gradual deceleration in follow mode conditions. Harsh braking by the target vehicle or following the target vehicle down to very low speeds or to a halt will require driver override of the brakes.
- While the radar sensor detects moving and stationary targets for assessment of the environment ahead, the system does not react to or provide any control in situations other than follow mode conditions. Stationary or slow moving vehicles (below 10 km/h), pedestrians, objects on the road and oncoming vehicles in the same lane are not recognized.

WARNING: It must be emphasized that the adaptive speed control system is not a collision warning or avoidance system and that, other than the limited conditions of follow mode, driver intervention will be necessary to control the vehicle speed.

In follow mode, some situations may cause target ambiguities for the detection system. These situations include:

- The nearby presence of a third vehicle when driving on a line slightly offset to the target vehicle.
- Vehicles edging into the lane ahead which are not detected by the system until they have moved into the radar beam.

On the approach to, or exit from a bend, a target vehicle may be lost or a new target acquired as vehicles ahead change their angular position with respect to the radar sensor. On a straight road, if the sensing vehicle is in follow mode below its selected set speed, losing the target vehicle will cause the sensing vehicle to accelerate to this set speed. This acceleration is undesirable either on, or entering a bend when the target is suddenly lost, and in this situation the system inhibits the resumption of the set speed.

The speed control system compares vehicle speed data from the [ABS](#) system with the relative speed of an external object as detected by the radar sensor to ascertain whether the object is stationary or not.

• **NOTE:** If tires are fitted which are different in diameter from those specified for the vehicle, the vehicle speed calculated by the [ABS](#) will not be the true road speed. This situation may cause stationary objects to be falsely identified as moving vehicles and result in automatic deceleration on a clear road.

Component Description

Speed Control Switches

E98448

ItemDescription

1	Set speed adjustment switch
2	Time gap switch
3	Cancel switch
4	Resume switch

The speed control switches are located on the RH (Right-hand) side of the steering wheel. The switches are connected via fly leads to the clock spring. The speed control switches are resistive ladder type switches which vary the resistance of a 5 volt signal sent to them. The signal is returned along a Lin bus to the instrument cluster. The instrument cluster routes the control signals to the [ECM](#) on the MS [CAN](#).

Speed control is engaged by rotating the speed adjustment switch to the + or - positions. Once engaged the speed can be varied by the speed adjustment switches. Each press of the speed adjustment switch will increase or decrease the set speed in steps of 1 mph (2 kph).

Adaptive Speed Control Module

E98450

The Adaptive Speed Control module, located on the drivers side at the bottom of the A post. The control module is connected to the other vehicle systems via the high speed [CAN](#) bus. Signals from the Adaptive Speed Control forward looking radar sensor are received on a dedicated [CAN](#) bus between the two modules.

Adaptive Speed Control Radar Sensor

E98451

The adaptive speed control radar sensor is located in the front bumper, on the RH side above the radiator grill behind the bumper cover. The sensor is connected to the Adaptive Speed Control, module via a private [CAN](#) bus. If the unit is replaced in service the unit must be re-aligned vertically. Horizontal alignment is achieved by putting the sensor in service mode via the recommended Jaguar diagnostic tool.

The vehicle is then driven for a short period while the sensor calibrates itself. Calibration is complete when the 'follow' icon in the instrument cluster stops flashing.

Forward Alert Switches

E98449

The forward alert system utilizes the Adaptive Speed Control system components. Forward alert is turned on and off independently of Adaptive Speed Control, via a switch mounted in the lower outboard knee bolster switchpack. Forward alert will notify the driver by means of a chime, and warning indicator in the instrument cluster and indication in the message center, when a target vehicle comes into range. The system will NOT use throttle or brake intervention to slow the vehicle.

The forward alert switch is connected to the instrument cluster in a resistive ladder with the luggage compartment opening switch and the fuel filler flap switch. The instrument cluster sends the forward alert information to the Adaptive speed control module on the [CAN](#) bus.

• **NOTE:** This system is intended as a driver aid and should be used as such. The system is NOT a collision warning or avoidance device.

The system sensitivity can be adjusted in the same manner as the Adaptive Speed Control, via the steering wheel mounted switches. Each adjustment is accompanied by a message in the message center.

Speed Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Speed Control

Diagnosis and Testing

Principles of Operation

For a detailed description of the speed control system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (310-03 Speed Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8)

[Speed Control](#) (Description and Operation),
[Speed Control](#) (Description and Operation),
[Speed Control](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. Verify the customer concern.
2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Speed control sensor ● Ensure the speed control sensor is free from obstructions ● Speed control module ● Brake switch 	<ul style="list-style-type: none"> ● Fuses ● Wiring harness ● Electrical connector(s) ● Steering wheel switches ● Brake switch ● Speed control sensor ● Speed control module ● Engine Control Module (ECM)

3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Speed Control Sensor Adjustment (vehicles with adaptive system installed)

An incorrectly aligned speed control sensor can cause incorrect system operation. Before starting any repair work on the speed control system, on vehicles with the adaptive system installed, check speed control sensor for correct vertical alignment, and carry out speed control sensor alignment procedure using manufacturer approved diagnostic system.

Symptom Chart

Symptom	Possible Cause	Action
Speed control inhibited or disabled	<ul style="list-style-type: none"> ● Power or ground supply to speed control module or speed control sensor ● Steering wheel speed control switch/circuits ● Throttle sensors ● Brake switch ● Anti-Lock Brake System fault 	<ul style="list-style-type: none"> ● Check for DTCs that could be caused by power or ground failure to the module or sensor and refer to DTC Index ● Check for sticking, jammed and broken speed control switches. DTC Index

Vehicles WITH Adaptive System Installed

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• **NOTE:** If a module or component is suspect, and the vehicle remains under the Manufacturers warranty, refer to the Warranty Policy and Procedure manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• **NOTE:** Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• **NOTE:** When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• **NOTE:** Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• **NOTE:** If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

Speed Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Speed Control Sensor Adjustment

General Procedures

Special Tool(s)

1.  CAUTION: Protect the surrounding paintwork to avoid damage.

2. 2. NOTE: Make sure that the vehicle is standing on a level surface.

E100511

3. **NOTE:** Make sure that the vehicle is standing on a level surface.

Special Tool(s): [501-F007](#)

4. **NOTE:** Do not release the lock nut.

- **NOTE:** Make sure that the vehicle is standing on a level surface.

Special Tool(s): [501-F007](#)

5.  **CAUTION:** Protect the surrounding paintwork to avoid damage.

6.
 - Configure the ACC module using the diagnostic tool.
 - This procedure is required if:
 - A new ACC radar and, or ACC module are installed.
 - The ACC radar needed to be removed or is misaligned in its position due to another repair operation.
7.
 - From the diagnostic tool menu, select: Service Alignment Mode.
 - The follow indicator will now be flashing, this indicates that the vehicle is in "service alignment" and now requires driving.
 - The vehicle speed must be above 30mph (48 kph).
 - Choose a road with plenty of stationary objects, like street lights, road signs, or barriers. Use an inside or outside lane.

- Following vehicles too closely will obscure the stationary targets from the radar, a time gap of 2 seconds is recommended.
- A straight road will produce a quicker and better result, although the process will still operate on a curved road.
- The time that the ACC module takes to align will vary, depending on the route, speed, number of targets, and individual module.
- When the flashing follow indicator light extinguishes, the ACC system is now functional, and a required vehicle speed can now be set by the driver and the ACC system will operate as normal.

Speed Control - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Speed Control Deactivator Switch

Climate Control System - General Information -

Lubricants, Fluids, Sealers and Adhesives

Description	Specification
Air conditioning refrigerant	HFC 134a
Air conditioning compressor oil	ND-OIL8

Capacities

Description	Grammes
Air conditioning refrigerant - All except vehicles with diesel engine	750
Air conditioning refrigerant - Vehicles with diesel engine	750

Refrigerant Oil Adding Capacities

Item	Milliliters
Condenser core and desiccant bag	Add 33
Desiccant bag	Add 8
Evaporator	Add 46
Air conditioning (A/C) compressor	Drain the oil from the new compressor and replace it with the same quantity as that drained from the compressor being replaced.
Air conditioning lines - If air conditioning has been operational.	Add 10 per line

Climate Control System - General Information - Climate Control System

Diagnosis and Testing

Principles of Operation

For a detailed description of the Climate Control system, refer to the relevant Description and Operation sections in the Workshop Manual. REFER to:

[Air Distribution and Filtering](#) (412-01 Climate Control, Description and Operation),
[Air Distribution and Filtering](#) (412-01 Climate Control, Description and Operation),
[Air Distribution and Filtering](#) (412-01 Climate Control, Description and Operation),

 Electric Booster Heater (412-02 Auxiliary Climate Control, Description and Operation),
 Electric Booster Heater (412-02 Auxiliary Climate Control, Description and Operation),
 Electric Booster Heater (412-02 Auxiliary Climate Control, Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Front End Accessory Drive (FEAD) belt ● Refrigerant ● Heater control flaps ● Ducting 	<ul style="list-style-type: none"> ● Fuse(s) ● Harness ● Electrical connectors ● Switch(s)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B105A01	Cabin Temperature Sensor Fan	<ul style="list-style-type: none"> ● Aspirator motor diagnostic circuit - short to ground, open circuit ● Aspirator fan component failure 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check aspirator motor diagnostic circuit for short to ground, open circuit
B108100	Left Temperature Damper Motor	<ul style="list-style-type: none"> ● Left hand blend stepper motor internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system

DTC	Description	Possible Cause	Action
B108149	Left Temperature Damper Motor	<ul style="list-style-type: none"> Left hand blend stepper motor internal electronic failure 	Suspect the left hand blend stepper motor. Check and install a new stepper motor as required, refer to the new module/component installation note at the top of the DTC Index
B108200	Right Temperature Damper Motor	<ul style="list-style-type: none"> Right hand blend stepper motor internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system
B108249	Right Temperature Damper Motor	<ul style="list-style-type: none"> Right hand blend stepper motor internal electronic failure 	Suspect the right hand blend stepper motor. Check and install a new stepper motor as required, refer to the new module/component installation note at the top of the DTC Index
B108301	Recirculation Damper Motor	<ul style="list-style-type: none"> RECIRC servo motor circuits - short to ground, power, open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check RECIRC servo motor circuit for short to ground, power, open circuit
B108500	Defroster Damper Motor	<ul style="list-style-type: none"> Defrost stepper motor internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system
B108549	Defroster Damper Motor	<ul style="list-style-type: none"> Defrost stepper motor internal electronic failure 	Suspect the defrost stepper motor. Check and install a new stepper motor as required, refer to the new module/component installation note at the top of the DTC Index
B108600	Air Distribution Damper Motor	<ul style="list-style-type: none"> Panel/foot stepper motor internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system
B108649	Air Distribution Damper Motor	<ul style="list-style-type: none"> Panel/foot stepper motor internal electronic failure 	Suspect the panel/foot stepper motor. Check and install a new stepper motor as required, refer to the new module/component installation note at the top of the DTC Index
B108788	LIN Bus "A"	<ul style="list-style-type: none"> LIN Bus power #1 circuit - open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check LIN Bus power #1 circuit for open circuit
B108888	LIN Bus "B"	<ul style="list-style-type: none"> LIN Bus power #2 circuit - open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check LIN Bus power #2 circuit for open circuit
B11ED68	Electric Heater Control Module	<ul style="list-style-type: none"> Event information. Electric heater - invalid communication message 	Clear DTC. With engine coolant temperature low, set climate temperature to high and re-test. If DTC remains in isolation suspect the PTC heater, check and install a new heater as required, refer to the new module/component installation note at the top of the DTC Index. If additional LIN related DTCs are logged refer to the Actions for these DTCs
B11ED87	Electric Heater Control Module	<ul style="list-style-type: none"> Electric heater - missing communication message 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system
B11ED96	Electric Heater Control Module	<ul style="list-style-type: none"> Component internal failure 	Suspect the PTC heater, check and install a new heater as required, refer to the new module/component installation note at the top of the DTC Index
B11ED98	Electric Heater Control Module	<ul style="list-style-type: none"> Component or system over temperature 	Clear DTC. With engine coolant temperature low, set climate temperature to high and re-test. If DTC remains suspect the PTC heater, check and install a new heater as required, refer to the new module/component installation note at the top of the DTC Index
B11EE01	A/C Compressor	<ul style="list-style-type: none"> Air conditioning compressor clutch solenoid circuits - short to ground, power, open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check air conditioning compressor clutch solenoid circuits for short to ground, power, open circuit
B11F011	Air Intake Damper Position Sensor	<ul style="list-style-type: none"> RECIRC servo motor air intake feedback and 5 volt supply circuits - short to ground 	Refer to the electrical circuit diagrams and check RECIRC servo motor air intake feedback and 5 volt supply circuits for short to ground
B11F015	Air Intake Damper Position Sensor	<ul style="list-style-type: none"> RECIRC servo motor air intake feedback and ground circuits - short to power, open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check RECIRC servo motor air intake feedback and ground circuits for short to power, open circuit
B11F800	Left Outer Vent	<ul style="list-style-type: none"> Left outer IP vent actuator internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system.
B11F849	Left Outer Vent	<ul style="list-style-type: none"> Left outer IP vent actuator internal electronic failure 	Suspect the left outer IP vent actuator. Check and install a new actuator as required, refer to the new module/component installation note at the top of the DTC Index

DTC	Description	Possible Cause	Action
B11F900	Left Inner Vent	<ul style="list-style-type: none"> Left inner IP vent actuator internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system.
B11F949	Left Inner Vent	<ul style="list-style-type: none"> Left inner IP vent actuator internal electronic failure 	Suspect the left inner IP vent actuator. Check and install a new actuator as required, refer to the new module/component installation note at the top of the DTC Index
B11FA00	Right Inner Vent	<ul style="list-style-type: none"> Right inner IP vent actuator internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system.
B11FA49	Right Inner Vent	<ul style="list-style-type: none"> Right inner IP vent actuator internal electronic failure 	Suspect the right inner IP vent actuator. Check and install a new actuator as required, refer to the new module/component installation note at the top of the DTC Index
B11FB00	Right Outer Vent	<ul style="list-style-type: none"> Right outer IP vent actuator internal or external fault 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system.
B11FB49	Right Outer Vent	<ul style="list-style-type: none"> Right outer IP vent actuator internal electronic failure 	Suspect the right outer IP vent actuator. Check and install a new actuator as required, refer to the new module/component installation note at the top of the DTC Index
B11FF84	A/C Refrigerant Pressure	<ul style="list-style-type: none"> Signal below allowable range. A/C System Refrigerant Pressure too low 	This DTC can be logged by the system due to low ambient temperature soak (below 3°C) reducing the pressure in the refrigerant gas system. If the cabin temperature logged along with the DTC at the time is below 10°C this could indicate low temperature. If the air conditioning performance is satisfactory and the in-cabin temperature is below 10°C then it is likely that the system contains a suitable amount of gas and the DTC is being recorded as an effect of the low ambient temperature. If this is not the case carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check air conditioning pressure sensor circuits for short, open circuit. Check for correct charge weight
B11FF85	A/C Refrigerant Pressure	<ul style="list-style-type: none"> Signal above allowable range. A/C System Refrigerant pressure too high 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check air conditioning pressure sensor circuits for short, open circuit
B1A5911	Sensor 5 Volt Supply	<ul style="list-style-type: none"> Air conditioning pressure sensor or RECIRC servo motor 5 volt supply circuits - short to ground 	Refer to the electrical circuit diagrams and check air conditioning pressure sensor and RECIRC servo motor 5 volt supply circuits for short to ground
B1A5913	Sensor 5 Volt Supply	<ul style="list-style-type: none"> Air conditioning pressure sensor 5 volt supply circuits - open circuit 	Refer to the electrical circuit diagrams and check air conditioning pressure sensor 5 volt supply circuit for open circuit
B1A6011	Pollution Sensor - Hydrocarbon	<ul style="list-style-type: none"> Pollution sensor hydrocarbon input circuit - short to ground 	Refer to the electrical circuit diagrams and check pollution sensor hydrocarbon input circuit for short to ground
B1A6111	Cabin Temperature Sensor	<ul style="list-style-type: none"> In car temperature sensor circuit - short to ground 	Refer to the electrical circuit diagrams and check In car temperature sensor circuit for short to ground
B1A6115	Cabin Temperature Sensor	<ul style="list-style-type: none"> In car temperature sensor circuit - short to power, open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check In car temperature sensor circuit for short to power, open circuit
B1A6311	Right Solar Sensor	<ul style="list-style-type: none"> Right sun load sensor signal circuit - short to ground 	Refer to the electrical circuit diagrams and check right sun load sensor signal circuit for short to ground
B1A6411	Left Solar Sensor	<ul style="list-style-type: none"> Left sun load sensor signal circuit - short to ground 	Refer to the electrical circuit diagrams and check left sun load sensor signal circuit for short to ground
B1A6713	Sensor Ground	<ul style="list-style-type: none"> Sensor ground circuits - open circuit 	Refer to the electrical circuit diagrams and check sensor ground circuits for open circuit
B1A6901	Humidity Sensor	<ul style="list-style-type: none"> Humidity sensor PWM input circuit - short to ground, power, open circuit Sensor component failure 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check humidity sensor PWM input circuit for short to ground, power, open circuit. Check and install a new sensor as required

DTC	Description	Possible Cause	Action
B1B6211	Pollution Sensor - NOx	<ul style="list-style-type: none"> ● Pollution sensor NOx input circuit - short to ground 	Refer to the electrical circuit diagrams and check pollution sensor NOx input circuit for short to ground
B1B7111	Evaporator Temperature Sensor	<ul style="list-style-type: none"> ● Evaporator temperature sensor signal circuit - short to ground 	Refer to the electrical circuit diagrams and check evaporator temperature sensor signal circuit for short to ground
B1B7115	Evaporator Temperature Sensor	<ul style="list-style-type: none"> ● Evaporator temperature sensor signal circuit - short to power, open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check evaporator temperature sensor signal circuit for short to power, open circuit
B1B7211	LIN Bus #1 Power Supply Circuit	<ul style="list-style-type: none"> ● Stepper motor circuit LIN Bus #1 power supply - short to ground 	Refer to the electrical circuit diagrams and check stepper motor circuit LIN Bus #1 power supply for short to ground
C1B1413	Sensor Supply Voltage A	<ul style="list-style-type: none"> ● RECIRC servo motor 5 volt supply circuit - open circuit 	Refer to the electrical circuit diagrams and check RECIRC servo motor 5 volt supply circuit for open circuit
C1B1513	Sensor Supply Voltage B	<ul style="list-style-type: none"> ● RECIRC servo motor and EVAP sensor ground circuits - open circuit 	Refer to the electrical circuit diagrams and check RECIRC servo motor and EVAP sensor ground circuits for open circuit
P053011	A/C Refrigerant Pressure Sensor A Circuit	<ul style="list-style-type: none"> ● Air conditioning pressure sensor signal circuit - short to ground 	Refer to the electrical circuit diagrams and check air conditioning pressure sensor signal circuit for short to ground
P053015	A/C Refrigerant Pressure Sensor A Circuit	<ul style="list-style-type: none"> ● Air conditioning pressure sensor signal circuit - short to power, open circuit 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to the electrical circuit diagrams and check air conditioning pressure sensor signal circuit for short to power, open circuit
U001088	Medium Speed CAN Communication Bus	<ul style="list-style-type: none"> ● Bus off 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system.
U030000	Internal Control Module Software Incompatibility	<ul style="list-style-type: none"> ● Invalid configuration message is received 	Re-configure the RJB using the manufacturer approved diagnostic system. Clear the DTC and retest. If the DTC is still logged suspect the climate control module, refer to the new module/component installation note at the top of the DTC Index
U1A1449	CAN Initialisation Failure	<ul style="list-style-type: none"> ● Internal electronic failure 	Suspect the climate control module, check and install a new module as required, refer to the new module/component installation note at the top of the DTC Index
U300055	Control Module	<ul style="list-style-type: none"> ● Incorrect car configuration data received 	Re-configure the RJB using the manufacturer approved diagnostic system. Clear DTC and re-test. If the DTC remains suspect the climate control module. Check and install a new module as required, refer to the new module/component installation note at the top of the DTC Index
U300087	Control Module	<ul style="list-style-type: none"> ● Missing message 	Re-configure the RJB using the manufacturer approved diagnostic system. Check climate control module for DTCs and refer to the DTC Index. Carry out CAN network integrity tests using the manufacturer approved diagnostic system. If DTC remains suspect the climate control module. Check and install a new module as required, refer to the new module/component installation note at the top of the DTC Index
U300281	Vehicle Identification Number	<ul style="list-style-type: none"> ● Vehicle/component mis-match. Corrupt VIN data being transmitted, module previously installed to other vehicle 	Check and install original/new module as required, refer to the new module/component installation note at the top of the DTC Index

Climate Control System - General Information - Air Conditioning (A/C) System Recovery, Evacuation and Charging

General Procedures

1.  **WARNING:** Servicing must be carried out by personnel familiar with both vehicle system and the charging and testing equipment. All operations must be carried out in a well ventilated area away from open flame and heat sources.

• **NOTE:** The receiver drier need only be changed under the following circumstances: There is dirt in the refrigerant circuit (eg. compressor seizure), the system is leaking and refrigerant has been lost to atmosphere, or the refrigerant circuit has been open more than 24 hours, due to repair.

Refrigerant recovery.

2. Remove the dust covers from the high and low pressure connections.

E97765

3. Connect the high and low pressure lines to the appropriate connections.

4. Open the valves on the connections.

5. Turn the valves on the station to the correct positions.

6. Turn the process switch to the correct position.

7. Turn the main switch to 'ON'.

8.  **WARNING:** Refrigerant must always be recycled before re-use to ensure that the purity of the refrigerant is high enough for safe use in the air conditioning system. Recycling should always be carried out with equipment which is design certified by Underwriter Laboratory Inc. for compliance with SEA J1991. Other equipment may not recycle refrigerant to the required level of purity. R143a Refrigerant Recover Recycling Recharging station must not be used with any other type of refrigerant. Refrigerant R134a from domestic and commercial sources must not be used in motor vehicles air conditioning systems.

Allow the system to recover the refrigerant from the system.

9. Close the valves on the refrigerant station.

10. Turn the main switch 'OFF'.

11. Close the valves on the connections.
12. Disconnect the high and low pressure connections.
13. Install the dust covers to the connectors.
14. Open the tap at the rear of the station to drain the refrigerant oil.
15. Measure and record the quantity of refrigerant oil recovered from the system.
16. Close the tap at the rear of the station.
17. Evacuation.
18. Remove the dust covers from the high and low pressure connections.
19. Connect the high and low pressure lines to the appropriate connections.
20. Open the valves on the connections.
21. Turn the valves on the station to the correct positions.
22. Turn the process switch to the correct position.
23. Turn the main switch to 'ON'.
24. Allow the station to evacuate the A/C system.
25.  **CAUTION:** The system must be evacuated immediately before recharging commences. Delay between evacuation and recharging is not permitted

Recharging

26. Close the valves on the refrigerant station.
27. Close the valve on the oil charger.
28. Disconnect the yellow line from the refrigerant station.
29. Remove the cover from the oil charger.
30. Pour the correct quantity of refrigerant oil into the oil charger.
31. Install the cover to the oil charger.
32. Connect the yellow line to the refrigerant station.
33. Open the valve on the oil charger.
34. Move the pointer on the refrigerant gauge to mark the position of the refrigerant drop.
35. Slowly open the correct valve on the refrigerant to allow the vacuum to pull the refrigerant into the system.
36. Close the valve on the refrigerant station when the correct amount of refrigerant has been drawn into the air conditioning system.
37. Turn the main switch 'OFF'.
38. Close the valves on the connections.
39. Disconnect the high and low pressure connections.

Climate Control System - General Information - Air Conditioning (A/C) System Flushing

General Procedures

1. WARNINGS:

Use extreme care and observe all safety precautions related to the use of refrigerants. Due to refrigerant hazards, always wear safety goggles and non-penetrable gloves when working on or flushing air conditioning (A/C) systems. Failure to follow this instruction may result in personal injury.

When flushing the A/C system, refer to the manufacturers equipment instructions for additional information. Failure to do so may result in system damage or personal injury.

The A/C refrigerant analyzer must be used before the recovery of any vehicle's A/C refrigerant. Failure to do so puts shop bulk refrigerant at risk of contamination. If the vehicle A/C refrigerant is contaminated, refer the customer to return to the repair facility that performed the last A/C repair. If the customer wishes to pay the additional cost, use the A/C recovery equipment that is designated for recovering contaminated A/C refrigerant. All contaminated A/C refrigerant must be disposed of as hazardous waste. For additional information, refer to the manufacturers equipment instructions. Failure to follow this instruction may result in personal injury.

Prior to using the A/C flushing equipment for the first time, follow the operating instructions. Failure to follow this instruction may result in personal injury.

CAUTION: Prior to flushing, remove and discard the desiccant sack. Depending on the equipment used, other A/C components may have to be removed prior to flushing. For additional information, refer to the manufacturers equipment instructions before flushing the A/C system.

Recover the refrigerant.

For additional information, refer to [Air conditioning \(A/C\) System Recovery, Evacuation and Charging](#) in this section.

2. Remove the desiccant sack.

For additional information, refer to Section [412-03 Air Conditioning](#).

3. Flush the system. For additional information, refer to the manufacturers equipment instructions.

4. Install new refrigerant lines if blocked with debris.

5. Install a new desiccant sack.

For additional information, refer to Section [412-03 Air Conditioning](#).

6. Add the required amount of oil to the A/C system depending on the repair procedure.

For additional information, refer to [Refrigerant Oil Adding](#) in this section.

7. Evacuate and charge the A/C system.

For additional information, refer to [Air conditioning \(A/C\) System Recovery, Evacuation and Charging](#) in this section.

8. Carry out fluorescent dye leak detection test.

For additional information, refer to [Flourescent Dye Leak Detection](#) in this section.

9. Check the A/C system for correct operation.

Climate Control System - General Information - Contaminated Refrigerant Handling

General Procedures

1. If contaminated refrigerant is detected DO NOT recover the refrigerant into your R-134a OR R-12 recovery/recycling equipment. Take the follow actions:
 1. Repeat the test to verify contaminated refrigerant is present.
 2. Advise the customer of the contaminated A/C system and any additional cost to repair the system. The customer may wish to return to the repair facility performing the last A/C repair.
 3. Recover the contaminated refrigerant using suitable recovery only equipment designed for capturing and storing contaminated refrigerant. This equipment must only be used to recover contaminated refrigerant to prevent the spread to other vehicles. As an alternative, contact an A/C repair facility in your area with the proper equipment to perform the repair.
 4. On completion of the recovery of the contaminated refrigerant, it will be necessary to carry out the A/C system flushing procedure.
For additional information, refer to [Air Conditioning \(AC\) System Flushing](#) in this section.

Climate Control System - General Information - Electronic Leak Detection

General Procedures

-  **WARNING:** Good ventilation is necessary in the area where A/C leak testing is to be carried out. If the surrounding air is contaminated with refrigerant gas, the leak detector will indicate this gas all the time. Odors from other chemicals such as antifreeze, diesel fuel, disc brake cleaner, or other cleaning solvents can cause the same problem. A fan, even in a well ventilated area, is very helpful in removing small traces of contamination from the air that might affect the leak detector. Failure to follow this instruction may result in personal injury.

Attach an R-134a manifold gauge set or use a UL-approved recovery/recycling device such as an R-134a A/C refrigerant center (which meets SAE Standard J 1991). For additional information, refer to the manufacturers equipment instructions.

- Both gauges should indicate 413-551 kPa (60-80 psi) at 24°C (75°F) with the engine off.
 - If little or no pressure is indicated, carry out the air conditioning (A/C) system recovery, evacuation and charging procedure.
For additional information, refer to [Air Conditioning \(AC\) System Recovery, Evacuation and Charging](#) in this section.
2. Use an R134-a Automatic calibration halogen leak detector to leak test the refrigerant system. For additional information, refer to the manufacturers equipment instructions.
 3. If a leak is found, carry out the air conditioning (A/C) system recovery procedure.
For additional information, refer to [Air Conditioning \(AC\) System Recovery, Evacuation and Charging](#) in this section.

Climate Control System - General Information - Fluorescent Dye Leak Detection

General Procedures

1. **WARNING:** Eye protection glasses supplied with the ultraviolet (UV) lamp should be used to protect eyesight from harm.

• **NOTE:** The air conditioning (A/C) system has an R-134a leak trace dye wafer incorporated into the desiccant bag. The exact location of leaks can be pinpointed by the bright yellow/green glow of the tracer dye. Since more than one leak may exist, always inspect each component. If it is necessary to add dye (due to a severe leakage for example) use proprietary tracer dye injection equipment.

Check for leaks using ultraviolet (UV) lamp.

2. Check all components, fittings and lines of the A/C system.
3. Carry out the repair. For additional information, refer to Section [412-03 Air Conditioning](#).
4. After the leak is repaired, remove any traces of leak trace dye with a general purpose oil solvent.
5. Check the A/C system for correct operation.
6. Verify the repair by operating the system for a short time and inspecting with the (UV) lamp.

Climate Control System - General Information - Inspection and Assembly Requirements

General Procedures

1. Check for leaks using ultraviolet (UV) Lamp.
For additional information, refer to [Flourescent Dye Leak Detection](#) in this section.
 2. NOTE: Any time a hose or component connection leak is observed, the component and fitting must be separated, cleaned and a new O-ring fitted and lubricated with air conditioning compressor oil.
For additional information, refer to [Specifications](#) in this section.
- NOTE: When separating A/C joints, cap the open connections immediately. Do not leave open to atmosphere.

O-ring seal surfaces must be free of dirt, lint, burrs and scratches. The O-ring and connector should be lubricated with air conditioning compressor oil.
For additional information, refer to [Specifications](#) in this section.

Climate Control System - General Information - Manifold Gauge Set Connection

General Procedures

1. WARNINGS:

Use extreme care and observe all safety precautions related to the use of refrigerants. Failure to follow this instruction may result in personal injury.

For additional information, refer to the manufacturers equipment instructions. Failure to follow this instruction may result in personal injury and system damage.

Install the manifold gauge set. For additional information, refer to the manufacturers equipment instructions.

2. Carry out the repair.

3. Remove the manifold gauge set. For additional information, refer to the manufacturers equipment instructions.

4. Carry out fluorescent dye leak detection test.
For additional information, refer to [Flourescent Dye Leak Detection](#) in this section.

5. Check air conditioning (A/C) system for correct operation.

Climate Control System - General Information - Refrigerant Oil Adding

General Procedures

CAUTION: Collect the refrigerant oil in a clean measuring cylinder.

1. **NOTE:** This step only needs to be carried out when removing the A/C compressor.

- **NOTE:** Rotate the compressor shaft at least 6 to 8 turns when draining the refrigerant oil.

Drain the refrigerant oil from the defective A/C compressor and dispose of it.

2. **CAUTIONS:**

The refrigerant oil top-up quantity must not exceed the refrigerant oil fill quantity.

If other A/C components are being renewed in addition to the A/C compressor, there is no need to top up with additional refrigerant oil, apart from filling the compressor.

Top up with the calculated quantity of new refrigerant oil.

Refer to: [Specifications](#) (412-00 Climate Control System - General Information, Specifications).

Climate Control System - General Information - Refrigerant System Tests

General Procedures

1. WARNINGS:

Use extreme care and observe all safety precautions related to the use of refrigerants. Failure to follow this instruction may result in personal injury.

The A/C refrigerant analyzer must be used before the recovery of any vehicle's A/C refrigerant. Failure to do so puts shop bulk refrigerant at risk of contamination. If the vehicle A/C refrigerant is contaminated, refer the customer to return to the repair facility that carried out the last A/C repair. If the customer wishes to pay the additional cost, use the A/C recovery equipment that is designated for recovering contaminated A/C refrigerant. All contaminated A/C refrigerant must be disposed of as hazardous waste. For all equipment, follow the equipment manufacturers procedures and instructions. Failure to follow this instruction may result in personal injury.

• NOTE: Jaguar Cars Ltd. supports the efficient usage, recovery and recycling of the refrigerant used in passenger car air conditioners. Jaguar Cars Ltd. recommends the use of UL-approved recovery/recycling device such as R-134a A/C refrigerant center (which meets SAE Standard J 1991) during any A/C system repair and recharge procedure which requires that the system be evacuated.

Use R-134a A/C Refrigerant Centre to evacuate and recover the A/C system.

- Follow the equipment manufactures procedures and instructions for use of equipment.

System Operation

Face Level Registers

Operation of the face level registers is controlled by the [ATC](#) module, using [LIN](#) bus messages to the integral stepper motors. The four registers operate together in both the opening and closing phases.

The face level registers can be selected to run in one of two modes; 'automatic' or 'always open'. The mode is selected on the climate control screen of the TSD.

Refer to: [Navigation System](#) (415-01 Information and Entertainment System, Description and Operation).

In the automatic mode, operation of the face level registers is synchronized with the engine START/STOP button. When the engine starts the [ATC](#) module opens the registers. When the engine stops, the [ATC](#) module closes the registers.

If a face level register is fouled, when it receives an open or close request, the register concerned makes a number of attempts to reach the requested position. If the register still does not move, it is left in the fouled position. The remaining registers will continue to open and close as normal.

The automatic mode is disabled when the climate control system is off. The [ATC](#) module closes the registers if they are open in the automatic mode and the climate control system is selected off.

Diagnostics

If a fault occurs with the face level registers, a [DTC \(diagnostic trouble code\)](#) is stored in the [ATC](#) module. The [DTC](#) can be read using the Jaguar approved diagnostic system. The Jaguar approved diagnostic system can also initiate a self test routine to check the operation of the face level registers.

Refer to: [Climate Control System](#) (412-00 Climate Control System - General Information, Diagnosis and Testing).

Component Description

Air Ducts

The air ducts distribute air from the heater assembly to the registers and vents in the instrument panel and the center floor console. Air ducts also direct air from the heater assembly into the front and rear footwells.

Registers and Vents

The registers control the flow and direction of air from the air ducts. The instrument panel contains four face level registers; one at each end and two mounted centrally. For the rear seat occupants, two registers are installed in the rear face of the center floor console. All of the registers incorporate vertical and horizontal directional vane adjustment and full air flow adjustment down to zero.

The four face level registers in the instrument panel each contain an integral stepper motor. The stepper motors enable the registers to rotate between the open and closed positions. In the open position, the registers have normal appearance and functionality. In the closed position, the registers present a smooth surface flush with the surrounding instrument panel.

The vents are fixed outlets. There are four vents in the upper surface of the instrument panel; one in each end to direct air onto the side windows and two along the front edge to direct air onto the windshield.

System Operation

Operation of the heating and ventilation system is controlled by the [ATC](#) module.
Refer to: [Control Components](#) (412-01 Climate Control, Description and Operation).

The system can be operated in automatic or manual mode, with temperature settings selected using the switches on the integrated control panel.

When the engine is running, coolant is constantly circulated through the heater core by the engine coolant pump and the auxiliary coolant pump. Where fitted, the auxiliary coolant pump is energized by the [CJB](#) on receipt of medium speed [CAN](#) bus signals from the [ATC](#) module. The [CJB](#) broadcasts auxiliary coolant pump status over the medium speed [CAN](#) bus for use by other vehicle systems.

The blower is supplied with power by the blower relay on the [RJB](#) and connected to ground via the blower control module. The blower control module regulates the voltage across the blower motor to control blower speed. The voltage set by the blower control module is controlled by a [PWM \(pulse width modulation\)](#) signal from the [ATC](#) module. The [ATC](#) module uses a feedback signal from the blower control module to monitor blower speed.
Refer to: [Control Components](#) (412-01 Climate Control, Description and Operation).

Component Description

Heater Assembly

The heater assembly controls the temperature and flow of air supplied to the air distribution ducts. The heater assembly is mounted on the vehicle centerline, between the instrument panel and the engine bulkhead.

The heater assembly consists of a casing that contains an [A/C \(air conditioning\)](#) evaporator, a heater core, two air distribution control doors and two temperature blend control doors. On 2.7L diesel vehicles, the heater assembly also contains an electric booster heater.
Refer to: Electric Booster Heater (412-02, Description and Operation).

Mounted on the heater casing are four stepper motors. Each of the stepper motors is connected to either an air distribution control door or a temperature blend control door.

The [A/C](#) evaporator is part of the [A/C](#) system.
Refer to: [Air Conditioning](#) (412-01 Climate Control, Description and Operation).

The heater core provides the heat source to warm the air supplied to the passenger compartment. The heater core is an aluminum two pass, fin and tube heat exchanger, and is installed across the width of the heater housing. Two aluminum tubes attached to the heater core extend through the engine bulkhead and connect to the engine cooling system. For additional information, refer to:

Engine Cooling (303-03A, Description and Operation),
Engine Cooling (303-03B, Description and Operation),
[Engine Cooling](#) (303-03A Engine Cooling - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Air Inlet Duct

The air inlet duct connects the fresh air inlet in the engine bulkhead to the heater assembly. The air inlet duct is installed behind the instrument panel on the passenger side.

The air inlet duct consists of a casing that contains a pollen filter, an air inlet door, a blower and a blower control module. A recirculation air inlet is incorporated into the casing. A servo motor is mounted on the casing and connected to the air inlet door, to allow selection between fresh and recirculated air.
Refer to: [Control Components](#) (412-01 Climate Control, Description and Operation).

The pollen filter is part of the air distribution and filtering system.
Refer to: [Air Distribution and Filtering](#) (412-01 Climate Control, Description and Operation).

The blower regulates the volume of air flowing through the air inlet duct to the heater assembly. The blower consists of an open hub, centrifugal fan and an electric motor.

The blower control module regulates the power supply to the blower motor. The blower control module is installed in the air inlet duct downstream of the blower, where any heat generated during operation is dissipated by the air flow.

Auxiliary Coolant Pump

On all vehicles except 3.0L, an auxiliary coolant pump is installed on the rear right side of the radiator housing, in the return line from the heater core. The auxiliary coolant pump is an electric pump that boosts the flow of coolant through the heater core.

Ventilation Outlets

The ventilation outlets allow the free flow of air through the passenger compartment. The outlets are installed in the LH and RH rear quarter panels, below the rear lamps. Each ventilation outlet consists of a grille covered by a soft rubber flap, and is effectively a non-return valve. The flaps open and close automatically depending on the pressure differential between the air inside and outside the vehicle.

Climate Control - Air Conditioning - Overview

Description and Operation

Overview

The [A/C \(air conditioning\)](#) system transfers heat from the passenger compartment to the outside atmosphere to provide the heater assembly with dehumidified cold air. It is a sealed, closed loop system filled with a charge weight of R134a refrigerant as the heat transfer medium. Oil is added to the refrigerant to lubricate the internal components of the [A/C](#) compressor.

Climate Control - Air Conditioning - System Operation and Component Description

Description and Operation

System Operation

General

To accomplish the transfer of heat, refrigerant is circulated around a sealed system, where it passes through two pressure/temperature regimes. In each of the regimes the refrigerant changes state, during which process maximum heat absorption or dissipation occurs.

The low pressure/temperature regime is from the thermostatic expansion valve, through the evaporator to the compressor. The refrigerant decreases in pressure and temperature at the thermostatic expansion valve, then changes state from a liquid to a vapor in the evaporator to absorb heat.

The high pressure/temperature regime is from the compressor, through the condenser and receiver drier assembly to the thermostatic expansion valve. The refrigerant increases in pressure and temperature as it passes through the compressor, then releases heat and changes state from a vapor to a liquid in the condenser.

Operation of the [A/C \(air conditioning\)](#) system is controlled by the [ATC \(automatic temperature control\)](#) module. Refer to: [Control Components](#) (412-01 Climate Control, Description and Operation).

The [A/C](#) system works in conjunction with:

- The air distribution and filtering system.
Refer to: [Air Distribution and Filtering](#) (412-01 Climate Control, Description and Operation).
- The heating and ventilation system.
Refer to: [Heating and Ventilation](#) (412-01 Climate Control, Description and Operation).

A/C Compressor

E46918

ItemDescription

1	Pressure relief valve
2	Outlet port
3	Inlet port
4	Solenoid valve
5	Electrical connector
6	Pulley

The [A/C](#) compressor circulates refrigerant around the system by compressing low pressure, low temperature vapor from the evaporator and discharging the resultant high pressure, high temperature vapor to the condenser.

The [A/C](#) compressor is a permanently engaged variable displacement unit which is driven by the engine accessory drive belt. To protect the system from excessive pressure, a pressure relief valve is installed in the outlet side of the [A/C](#) compressor. The pressure relief valve vents excess pressure into the engine compartment.

Condenser

E72963

ItemDescription

1	RH (right-hand) end tank
2	Condenser core
3	LH (left-hand) end tank
4	Mounting brackets (4 off)
5	High pressure compressor discharge line connector block
6	High pressure liquid outlet line connector block
7	Receiver/Drier outlet pipe
8	Receiver/Drier inlet pipe
9	Receiver/Drier

The condenser transfers heat from the refrigerant to the surrounding air to convert the high pressure vapor from the compressor into a liquid. The condenser is installed immediately in front of the radiator. Two brackets on each end tank attach the condenser to the end tanks of the radiator.

The condenser is classified as a sub-cooling condenser and consists of a fin and tube heat exchanger core installed between two end tanks. Divisions in the end tanks separate the heat exchanger into a four pass upper (condenser) section and a two pass lower (sub-cooler) section.

The LH end tank provides the connections to the high pressure line from the A/C compressor and the high pressure liquid line to the evaporator.

The RH end tank provides the connections to the receiver drier.

Receiver Drier

The receiver drier is integrated into the RH end tank of the condenser to remove solid impurities and moisture from the refrigerant. It also provides a reservoir for liquid refrigerant to accommodate changes of heat load at the evaporator.

• NOTE: The receiver drier is part of the condenser assembly and is not serviceable separately.

Refrigerant entering the receiver drier passes through a filter and a desiccant pack, then collects in the base of the unit before flowing through the outlet pipe back to the condenser.

Refrigerant Pressure Sensor

E43581

The refrigerant pressure sensor is located in the high pressure/temperature refrigerant line between the condenser and the thermostatic expansion valve.

Refer to: [Control Components](#) (412-01 Climate Control, Description and Operation).

Thermostatic Expansion Valve

E46922

ItemDescription

1	Metering valve
2	Housing
3	Diaphragm
4	Temperature sensor
5	Outlet passage from evaporator
6	Inlet passage to evaporator

The thermostatic expansion valve meters the flow of refrigerant into the evaporator, to match the refrigerant flow with the heat load of the air passing through the evaporator.

The thermostatic expansion valve is a block type valve located behind the heater assembly, and attached to the inlet and outlet ports of the evaporator. The thermostatic expansion valve consists of an aluminium housing containing inlet and outlet passages. A ball and spring metering valve is installed in the inlet passage and a temperature sensor is installed in the outlet passage. The temperature sensor consists of a temperature sensitive tube connected to a diaphragm. The bottom end of the temperature sensitive tube acts on the ball of the metering valve. Pressure on top of the diaphragm is controlled by the evaporator outlet temperature conducted through the temperature sensitive tube. The bottom of the diaphragm senses evaporator outlet pressure.

Liquid refrigerant flows through the metering valve into the evaporator. The restriction across the metering valve reduces the pressure and temperature of the refrigerant. The restriction also changes the liquid stream of refrigerant into a fine spray, to improve the evaporation process. As the refrigerant passes through the evaporator, it absorbs heat from the air flowing through the evaporator. The increase in temperature causes the refrigerant to vaporise and increase in pressure.

The temperature and pressure of the refrigerant leaving the evaporator acts on the diaphragm and temperature sensitive tube, which regulate the metering valve opening and so control the volume of refrigerant flowing through the evaporator. The warmer the air flowing through the evaporator, the more heat available to evaporate refrigerant and thus the greater volume of refrigerant allowed through the metering valve.

Evaporator

E46923

The evaporator is installed in the heater assembly, between the blower and the heater matrix, to absorb heat from the exterior or recirculated air.

Most of the moisture in the air passing through the evaporator condenses into water, which drains out of the vehicle by passing through a drain tube to the underside of the vehicle.

Refrigerant Lines

To maintain similar flow velocities around the [A/C](#) system, the diameter of the refrigerant lines varies to suit the two pressure/temperature regimes. Larger diameter pipes are installed in the low pressure/temperature regime and smaller diameter pipes are installed in the high pressure/temperature regime.

Low and high pressure charging connections are incorporated into the refrigerant lines for system servicing.

Climate Control - Control Components - Overview

Description and Operation

Overview

The climate control system is controlled by the [ATC \(automatic temperature control\)](#) module. It controls the heating and ventilation system and the [A/C \(air conditioning\)](#) system to regulate the temperature, volume and distribution of air into the passenger compartment. The system is a fully automatic dual zone system capable of maintaining individual temperature levels selected for the [LH \(left-hand\)](#) and [RH \(right-hand\)](#) sides of the passenger compartment, up to a maximum differential of approximately 3 °C (5.4 °F). Manual overrides for the system include inlet air source, blower speed and air distribution. These selections can be made using either the soft switches on the home and climate control screens of the touch screen display (TSD), or the switches on the integrated control panel.

The [ATC](#) module also controls:

- The rear window heater.
- The windshield heater (where fitted).
- The exterior mirror heaters.
- The seat heaters (where fitted).
- The steering wheel heater.

System Operation

Air Inlet Control

The source of inlet air is automatically controlled unless overridden by pressing the air recirculation switch on the integrated control panel. During automatic control, the [ATC](#) module determines the required position of the recirculation door from its 'comfort' algorithm and, if fitted, the pollution sensor.

The [ATC](#) module provides analogue signals to the air inlet servo motor along a hardwired connection. A potentiometer in the motor supplies the [ATC](#) module with a position feedback signal for closed loop control.

Air Temperature Control

Cooled air from the evaporator enters the heater assembly, where temperature blend doors direct a proportion of the air through the heater core to produce the required output air temperature.

The two temperature blend doors operate independently to enable individual temperature settings for the left and right sides of the passenger compartment. The temperature blend doors are operated by stepper motors, which are controlled by the [ATC](#) module using [LIN](#) bus messages.

The [ATC](#) module calculates the temperature blend stepper motor positions required to achieve the selected temperature and compares it against the current position. If there is any difference, the [ATC](#) module signals the stepper motors to adopt the new position.

Air temperature is controlled automatically unless maximum heating (HI) or maximum cooling (LO) is selected. When maximum heating or cooling is selected, a 'comfort' algorithm in the [ATC](#) module adopts an appropriate strategy for air distribution, blower speed, and air source.

Temperature control in one side of the passenger compartment can be compromised by the other side of the passenger compartment being set to a high level of heating or cooling. True maximum heating or cooling (displayed as 'HI' or 'LO' on the TSD) can only be selected for the driver's side of the passenger compartment. If 'HI' or 'LO' is selected for the driver's side, the temperature for the front passenger's side is automatically set to match the driver's side.

If [A/C](#) is selected off in the automatic mode, no cooling of the inlet air will take place. The minimum output air temperature from the system will be ambient air temperature plus any heat pick up in the air inlet path.

If the Temp. sync. soft button on the TSD is pressed, the [ATC](#) module synchronizes the temperature of the passenger side of the passenger compartment with the driver's side.

Blower Control

When the system is in the automatic mode, the [ATC](#) module determines the blower speed required from a comfort algorithm. When the system is in the manual mode, the [ATC](#) module operates the blower at the speed selected using either the rotary control switch on the integrated control panel or the + and - soft buttons on the touch screen display (TSD). The [ATC](#) module also adjusts blower speed to compensate for the ram effect on inlet air produced by forward movement of the vehicle. As vehicle speed and ram effect increases, blower motor speed is reduced, and vice versa.

Air Distribution Control

Two air distribution doors are used to direct air into the passenger compartment. The doors are operated by stepper motors, which are controlled by the [ATC](#) module using [LIN](#) bus messages.

When the [A/C](#) system is in automatic mode, the [ATC](#) module automatically controls air distribution into the passenger compartment in line with its 'comfort' algorithm. Automatic control is overridden if any of the TSD air distribution soft buttons are selected. Air distribution in the passenger compartment will remain as selected until the 'Auto' switch is pressed or a different manual selection is made.

A/C Compressor Control

When [A/C](#) is selected the [ATC](#) module maintains the evaporator at an operating temperature that varies with the passenger compartment cooling requirements. If the requirement for cooled air decreases, the [ATC](#) module raises the evaporator operating temperature by reducing the flow of refrigerant provided by the [A/C](#) compressor. The [ATC](#) module closely controls the rate of temperature increase to avoid introducing moisture into the passenger compartment.

If the requirement for cooled air increases, the [ATC](#) module lowers the evaporator operating temperature by increasing the flow of refrigerant provided by the [A/C](#) compressor.

When [A/C](#) is off, the compressor current signal supplied by the [ATC](#) module holds the [A/C](#) compressor solenoid valve in the minimum flow position, effectively switching off the [A/C](#) function.

The [ATC](#) module incorporates limits for the operating pressure of the refrigerant system. If the system approaches the high pressure limit, the compressor current signal is progressively reduced until the system pressure decreases. If the system falls below the low pressure limit, the compressor current signal is held at its lowest setting so that the [A/C](#) compressor is maintained at its minimum stroke. This avoids depletion of the lubricant from the [A/C](#) compressor.

A/C Compressor Torque

The [ATC](#) module transmits refrigerant pressure and [A/C](#) compressor current values to the [ECM \(engine control module\)](#) over the medium speed then high speed [CAN](#) bus, using the [CJB](#) as a gateway. The [ECM](#) uses these values to calculate the torque being used to drive the [A/C](#) compressor. The [ECM](#) compares the calculated value with its allowable value and if necessary forces the [ATC](#) module to inhibit the [A/C](#) compressor by transmitting the 'ACClutchInhibit' [CAN](#) message. This forces the [ATC](#) module to reduce the drive current to the [A/C](#) compressor solenoid valve, which reduces refrigerant flow. This in turn reduces the torque required to drive the [A/C](#) compressor.

By reducing the maximum [A/C](#) compressor torque, the [ECM](#) is able to reduce the load on the engine when it needs to maintain vehicle performance or cooling system integrity.

Cooling Fan Control

The [ATC](#) module determines the amount of condenser cooling required from the refrigerant pressure sensor, since there is a direct relationship between the temperature and pressure of the refrigerant. The cooling requirement is broadcast to the [ECM](#) on the medium speed [CAN](#) bus. The [ECM](#) then controls the temperature of the condenser using the cooling fan.

Programmed Defrost

The programmed defrost DEF switch is located on the integrated control panel. When the switch is pressed, the [ATC](#) module instigates the programmed defrost function. When selected, the [ATC](#) module configures the system as follows:

- Automatic mode off.
- [A/C](#) on.
- Selected temperature unchanged.
- Air inlet set to fresh air.
- Air distribution set to windshield.
- Blower speed set to level 6.
- Windshield heater (where fitted) and rear window heater on.

The programmed defrost function can be cancelled by one of the following:

- Selecting any air distribution switch on the TSD.
- Pressing the AUTO switch on the integrated control panel.
- A second press of the DEF button.
- Switching the ignition OFF.

The blower speed can be adjusted without terminating the programmed defrost function.

Rear Window Heater

Rear window heater operation is only enabled when the engine is running. The [ATC](#) module controls operation of the rear window heater using a relay in the [RJB](#). When rear window heater operation is required, the [ATC](#) module broadcasts a message to the [RJB](#) on the medium speed [CAN](#) bus. On receipt of the message, the [RJB](#) energizes the relay by providing a ground path for the relay coil. This allows a battery feed to flow across the relay to power the rear window heater element.

There are two modes of rear window heater operation; manual and automatic.

Manual operation is activated by pressing the rear window heater switch on the integrated control panel. When the switch is pressed, the status [LED \(light emitting diode\)](#) in the switch illuminates and the rear window heater element is energized. Manual operation is discontinued when the rear window heater switch is pressed a second time, 21 minutes have elapsed (the heating phase), or the engine stops. If manual operation is discontinued by the engine stopping, the previous heating phase is resumed if the engine is re-started within 30 seconds.

There are two variants of automatic operation; automatic operation at the start of a journey and automatic operation during a journey.

Automatic operation at the start of a journey is initiated if the ambient air temperature is below 5 °C (41 °F). In this instance, the switch [LED](#) is illuminated and the heater element is energized for 21 minutes. Automatic operation is discontinued if the rear window heater switch is pressed or the engine stops.

Automatic operation during a journey is initiated when low ambient air temperatures are experienced and the vehicle has been travelling for a set period of time above a threshold speed. In this instance, no feedback is given to the driver to inform him the rear window heater is operational (the switch [LED](#) is not illuminated). The duration of heater operation is variable depending on the ambient air temperature, vehicle speed and the amount of time the vehicle has been travelling.

Windshield Heater (Where Fitted)

Windshield heater operation is only enabled when the engine is running. The [ATC](#) module controls operation of the windshield heater using two relays in the [EJB \(engine junction box\)](#). When windshield heater operation is required, the [ATC](#) module broadcasts a message to the [CJB](#) on the medium speed [CAN](#) bus. On receipt of the message, the [CJB](#) energizes the relays by providing a ground path for both relay coils. This allows a battery feed to flow across the relays to power the windshield left and right heater elements.

There are two modes of windshield heater operation; manual and automatic.

Manual operation is activated by pressing the windshield heater switch on the integrated control panel. When the switch is pressed, the status [LED](#) in the switch illuminates and the windshield heater elements are energized. Manual operation is discontinued when the windshield heater switch is pressed a second time, 5 minutes have elapsed (the heating phase), or the engine stops. If manual operation is discontinued by the engine stopping, the previous heating phase is resumed if the engine is re-started within 30 seconds.

There are two variants of automatic operation; automatic operation at the start of a journey and automatic operation during a journey.

Automatic operation at the start of a journey is initiated if the ambient air temperature is below 5 °C (41 °F). In this instance, the switch [LED](#) is illuminated and the heater elements are energized for 6.5 minutes. Automatic operation is discontinued if the windshield heater switch is pressed or the engine stops.

Automatic operation during a journey is initiated when low ambient air temperatures are experienced and the vehicle has been travelling for a set period of time above a threshold speed. In this instance, no feedback is given to the driver to inform him the windshield heater is operational (the switch [LED](#) is not illuminated) and the duration of operation is variable depending upon the ambient air temperature, vehicle speed and the amount of time the vehicle has been travelling.

Exterior Mirror Heaters

Operation of the exterior mirror heaters is fully automatic and not controllable by the driver. Exterior mirror heater operation is determined by ambient air temperature and windshield wiper status. When ambient air temperature reaches a pre-determined level, the [ATC](#) module broadcasts an exterior mirror heating request to the door modules over the medium speed [CAN](#) bus. On receipt of this message, the door modules provide feed and ground connections to both exterior mirror heater elements.

The amount of time the exterior mirror heaters are operational increases if the windshield wipers are switched on. This ensures the mirrors remain mist free in damp and wet conditions, where there is an increased risk of misting.

Seat Heaters (Where Fitted)

There are four seat heater settings available; off, 1, 2 and 3, which can be selected on the home and climate control screens of the TSD. The heat setting is relayed to the vehicle occupants through a graduated display on the TSD.

Operation of the heated seats is controlled by the [ATC](#) module. When the [ATC](#) module receives a heating request from the TSD, it broadcasts a message to the [CJB](#) over the medium speed [CAN](#) bus. The [CJB](#) then provides a hardwired 12 V supply to the three heater elements in the related front seat. The heater elements, two in the seat cushion and one in the seat squab, are wired in series. The [ATC](#) module monitors seat temperature using a temperature sensor located in each seat cushion. The [CJB](#) provides the temperature sensors with a 5 V supply. The level of the returned voltage back to the [CJB](#) is proportional to the seat temperature. The value of the return signal is broadcast to the [ATC](#) module, over the medium speed [CAN](#) bus, which allows it to control the seat temperature to the required level. The [ATC](#) module will suspend or disable operation of the seat heaters if any of the following occur:

- Battery voltage exceeds 16.5 ± 0.3 V for more than 5 seconds. Seat heating is re-enabled when battery voltage decreases to 16.2 ± 0.3 V.
- If a short or open circuit is detected.
- If the seat heat temperature rises significantly above the target temperature setting.

The graduated display on the TSD remains illuminated until the seat heaters are turned off or the engine stops. If the engine is restarted within 30 seconds the seat heater resumes the previous heating level.

Steering Wheel Heater

The steering wheel heater has a single heat setting and is turned on/off on the home and climate control screens of the TSD. The on/off status of the steering wheel heater is relayed to the vehicle occupants through the TSD. When the ignition is switched off, the steering wheel heater will reset to off.

Power for the heater element is supplied by the [CJB](#) on receipt of a request from the [ATC](#) module over the medium speed [CAN](#) bus. Temperature control for the heater element is provided by the steering wheel heater control module which receives a temperature feedback signal from a [NTC \(negative temperature coefficient\)](#) thermistor located within the steering wheel.

Component Description

ATC Module

E97625

The [ATC](#) module is mounted on the outboard end of the air inlet duct, behind the front passenger side of the instrument panel. The [ATC](#) module processes inputs from the TSD, the switches on the integrated control panel and the system sensors. In response to these inputs, the [ATC](#) module outputs control signals to the [A/C](#) system and the heating and ventilation system.

Two electrical connectors provide the interface between the [ATC](#) module and the vehicle wiring. The [ATC](#) module uses hardwired inputs from the system sensors, the [LIN](#) bus to communicate with the stepper motors and the medium speed [CAN](#) bus to communicate with other control modules on the vehicle.

A/C Compressor Solenoid Valve

The [A/C](#) compressor solenoid valve is integral with the [A/C](#) compressor. Operation of the solenoid valve is controlled by the [ATC](#) module using a hardwired drive current of differing values. By controlling the flow of refrigerant through the compressor, the solenoid valve can control the [A/C](#) system pressure and the evaporator operating temperature.

Refrigerant Pressure Sensor

E43581

The refrigerant pressure sensor provides the [ATC](#) module with a pressure input from the high pressure side of the refrigerant system. The refrigerant pressure sensor is located in the refrigerant line between the condenser and the thermostatic expansion valve.

The [ATC](#) module supplies a 5 V reference voltage to the refrigerant pressure sensor and receives a return signal voltage, between 0 V and 5 V, related to system pressure.

The [ATC](#) module uses the signal from the pressure sensor to protect the refrigerant system from extremes of pressure. The [ATC](#) module transmits the [A/C](#) pressure, along with the compressor drive current value, to the instrument cluster on the medium speed [CAN](#) bus. These signals are broadcast to the [ECM](#) on the high speed [CAN](#) bus to allow it to calculate the torque being applied to the engine by the compressor.

To protect the system from extremes of pressure, the [ATC](#) module sets the [A/C](#) compressor to the minimum flow position if the pressure:

- Decreases to 2.1 ± 0.2 bar (31.5 ± 3 lbf/in²); the [ATC](#) module loads the [A/C](#) compressor again when the pressure increases to 2.3 ± 0.2 bar (33.4 ± 3 lbf/in²).
- Increases to 31 ± 1 bar (450 ± 14.5 lbf/in²); the [ATC](#) module loads the [A/C](#) compressor again when the pressure decreases to 26 ± 1 bar (377 ± 14.5 lbf/in²).

Evaporator Temperature Sensor

E97626

The evaporator temperature sensor is a [NTC](#) thermistor that provides the [ATC](#) module with a temperature signal from the downstream side of the evaporator. The evaporator temperature sensor is mounted directly onto the evaporator matrix fins.

The [ATC](#) module uses the input from the evaporator temperature sensor to control the load of the [A/C](#) compressor and thus the operating temperature of the evaporator.

Humidity and Temperature Sensor

E97627

The humidity and temperature sensor is installed above the glovebox in the instrument panel. The sensor incorporates:

- A [NTC](#) thermistor to measure temperature.
- A capacitive sensor element to measure humidity.
- A motor driven fan to draw air through the sensor and over the sensing elements.

The humidity sensor element is built out of a film capacitor on different substrates. The dielectric is a polymer which absorbs or releases water proportional to the relative humidity of the air being drawn through the sensor, and thus changes the capacitance of the capacitor. For protection, the sensor element is contained in a nylon mesh cover.

Humidity within the passenger compartment is controlled by raising and lowering the evaporator temperature. An increase in evaporator temperature increases the moisture content of the air entering the passenger compartment. Lowering the evaporator temperature reduces the moisture content of the air entering the passenger compartment.

Ambient Air Temperature Sensor

E97628

ItemDescription

1 [LH](#) door mirror

2 Ambient air temperature sensor

The ambient air temperature sensor is a [NTC](#) thermistor that provides the [ATC](#) module with an input of external air temperature. The sensor is hard wired to the [ECM](#) and its signal is transmitted to the instrument cluster on the high speed [CAN](#) bus. The instrument cluster acts as a gateway and transmits the ambient air temperature signal to the [ATC](#) module on the medium speed [CAN](#) bus. The sensor is installed in the [LH](#) door mirror, and is accessed by removing the mirror glass, cap and actuator.

Sunload Sensor

E71886

The sunload sensor consists of two photoelectric cells that provide the [ATC](#) module with inputs of light intensity; one as sensed coming from the left of the vehicle and one as sensed coming from the right. The inputs are a measure of the solar heating effect on vehicle occupants, and are used by the [ATC](#) module to adjust blower speed, temperature and distribution to improve comfort.

The sensor is installed in the speaker grill on the upper surface of the instrument panel. Power for the sensor is provided by a 5 V feed from the instrument cluster.

The sensor also contains the active anti-theft alarm indicator.

Refer to: Anti-Theft - Active (419-01 Anti-Theft - Active, Description and Operation).

Pollution Sensor (Where Fitted)

E43588

The pollution sensor allows the [ATC](#) module to monitor the ambient air for the level of hydrocarbons and oxidized gases such as nitrous oxides, sulphur oxides and carbon monoxide. The sensor is attached to the center of the upper front crossmember.

The pollution sensor is powered by an ignition controlled voltage feed from the [CJB](#) and provides the [ATC](#) module with separate signals of hydrocarbon and oxidized gas levels. With a pollution sensor fitted, the [ATC](#) module can control the air inlet source to reduce the amount of contaminants entering the passenger compartment. This function is fully automatic, but can be overridden by manual selection of the air source using the recirculation switch on the integrated control panel.

If there is a fault with the sensor, the [ATC](#) module disables automatic operation of the recirculation door.

Climate Control - Ambient Air Temperature Sensor

Removal and Installation

Removal

- NOTE: Removal steps in this procedure may contain installation details.

1. Refer to: [Exterior Mirror Cover](#) (501-09 Rear View Mirrors, Removal and Installation).

Instrument Cluster - Instrument Cluster - Overview

Description and Operation

OVERVIEW

The primary task of the instrument cluster is to display current vehicle status through a series of analogue gauges, indicator lamps, and a [LCD \(liquid crystal display\)](#) message center. In addition to this, the instrument cluster:

- Acts as a gateway between the medium speed and high speed [CAN \(controller area network\)](#) bus networks
- Is connected by the [LIN \(local interconnect network\)](#) bus to the start control unit and the steering wheel clockspring
- Controls operation of the steering column adjust feature
Refer to: [Steering Column](#) (211-04 Steering Column, Description and Operation).
- Acts as an interface for the passive anti-theft system.
Refer to: [Anti-Theft - Active](#) (419-01A Anti-Theft - Active, Description and Operation).

Two analogue gauges are located in the instrument cluster; the speedometer and the tachometer. The speedometer is located on the [LH \(left-hand\)](#) side of the instrument cluster. The tachometer is located on the [RH \(right-hand\)](#) side of the instrument cluster

and displays engine speeds up to 7000 Revolutions Per Minute (RPM) for the supercharged engine, 8000 RPM for the naturally aspirated engines and 6000 RPM for diesel variants.

The message center is a [LCD](#) located in a central position in the cluster. The message center displays system status information including fuel quantity remaining.

System Operation

WARNING INDICATOR FUNCTIONALITY

E99113

ItemDescription

1	LH turn signal
2	RH turn signal
3	Brake warning
4	Brake warning (NAS)
5	Forward alert
6	Automatic Speed Limiter (ASL)
7	Adaptive speed control
8	ABS (anti-lock brake system) warning
9	ABS warning (NAS)
10	Malfunction Indicator Lamp (MIL)
11	Tire Pressure Monitoring System (TPMS)
12	Airbag warning
13	Front fog lamps
14	Dynamic Stability Control (DSC) warning
15	Seat belt warning
16	Side lamps
17	High beam
18	Rear fog lamps

The functionality for each of the above warning indicators is described in the following sections:

1 and 2. Turn Signal Indicators

The turn signal indicators are controlled by the [CJB](#) on receipt of medium speed [CAN](#) bus signals from the instrument cluster.

The instrument cluster outputs a voltage to the turn signal indicator switch. The switch contains resistors of different values. When the switch is operated in either the [LH](#) or [RH](#) direction, the voltage is passed to a ground connection in the instrument cluster which detects the reduced voltage supplied via the resistors. When the turn signal indicator switch is operated in the [LH](#) or [RH](#) direction, the instrument cluster detects the ground voltage and determines whether a [LH](#) or [RH](#) selection is made.

The instrument cluster transmits a medium speed [CAN](#) message to the [CJB](#) for operation of the applicable turn signal

indicators. The message can contain a number of states for each possible switch position and also an out of range low and high state for circuit faults and an initial value for the switch neutral position. The turn signal indicators are not subject to the 3 second indicator check when the ignition is switched on.

The **RJB (rear junction box)** software controls the flash rate of the warning indicator which sends 'ON' and 'OFF' signals to the instrument cluster which flashes the indicators in a green color. During normal operation, the warning indicator flashes slowly, accompanied simultaneously by a sound from the instrument cluster sounder. If a fault exists, the **RJB** transmits a message to the instrument cluster which responds by displaying an appropriate message in the message center.

The hazard warning indicators are controlled by the **CJB** on receipt of a completed ground path from the hazard warning indicator switch. The **CJB** outputs a medium speed **CAN** message to the instrument cluster which operates both the **LH** and **RH** turn signal indicators simultaneously. The hazard warning indicators can operate with the ignition switched off, therefore the **CAN** message from the **CJB** will also carry a 'wake-up' message for the instrument cluster.

3. Brake Warning Indicator

This warning indicator is displayed in a red or amber color (dependant on market) as a brake symbol in all markets except United States of America (USA) which have the word 'BRAKE' in place of the symbol. The indicator is controlled by high speed **CAN** messages from the **ABS** module and the parking brake control module. The indicator is illuminated in a red color for a 3 second indicator check when the ignition is switched on.

The instrument cluster monitors the fluid level in the brake fluid reservoir using a hardwired level switch. If the fluid level falls to below a determined level, the switch contact is broken and the **ABS** module detects the low fluid level condition. The instrument cluster illuminates the warning indicator and simultaneously displays a 'BRAKE FLUID LOW' message in the message center.

- **NOTE:** If both the brake warning indicator and the **ABS** warning indicator illuminate simultaneously, a major fault in the brake system will have occurred.

The warning indicator also displays parking brake status. When the parking brake is applied, the warning indicator will be illuminated by the instrument cluster and, if the vehicle is moving, the message 'PARK BRAKE APPLIED' will be also displayed in the message center in response to a **CAN** message from the parking brake control module.

If a condition exists where the parking brake cannot be applied, the parking brake control module issues a **CAN** message to the instrument cluster which flashes the warning lamp on and off and is accompanied with a message 'CANNOT APPLY PARK BRAKE'. If a fault occurs in the parking brake system, the parking brake control module issues a **CAN** message to the instrument cluster which illuminates the warning indicator and displays the message 'PARK BRAKE FAULT' in the message center.

4. Forward Alert Indicator

The forward alert system uses the components of the adaptive speed control system to alert the driver of the presence of a vehicle ahead. The system can be turned on and off using a switch located in the auxiliary lighting switch when the adaptive speed control system is off. The indicator is illuminated in an amber color for a 3 second indicator check when the ignition is switched on.

The forward alert system is controlled by the adaptive speed control module. When the switch is pressed, the forward alert system is activated and the adaptive speed control module issues a forward alert active message on the high speed **CAN** bus to the instrument cluster. The forward alert icon in the instrument cluster will illuminate in an amber color and a 'FORWARD ALERT' message will be displayed in the message center. When the button is pressed a second time, the module issues a forward alert off **CAN** message. The forward alert system will be deactivated, the forward alert icon will go off and a message 'FORWARD ALERT OFF' will be displayed in the message center.

5. Automatic Speed Limiter (ASL) Indicator

The ASL is controlled by the **ECM (engine control module)**. An ASL switch is located in the floor console, adjacent to the gear selector lever. When the ASL switch is pressed, this is sensed by the **ECM** which issues a high speed **CAN** message to the instrument cluster. The instrument cluster illuminates the ASL warning indicator in an amber color to show the driver that ASL is active. The driver sets the required speed using the speed control SET +/- switches on the steering wheel. The selected speed is shown by the message 'LIMITER SET XXX MPH / K/MH' in the message center. The indicator is illuminated in an amber color for a 3 second indicator check when the ignition is switched on. ASL can be deselected by pressing the ASL switch, by depressing the throttle pedal initiating kick-down or by pressing the 'cancel' switch on the steering wheel. The ASL indicator will go off and the message center will display the message 'limiter cancelled' for 4 seconds. If a fault occurs in the ASL system, the **ECM** will send a message to the instrument cluster to illuminate the ASL indicator and display the message 'LIMITER NOT AVAILABLE'.

6. Adaptive Speed Control Indicator

The adaptive speed control system is controlled by the adaptive speed control module. Operation of the SET +/- switches on the steering wheel will activate the system. Operation of the switches is detected by the adaptive speed control module. The module issues a high speed **CAN** message to the instrument cluster which illuminates the adaptive speed control indicator, when the system is in 'follow mode', in an amber color and displays a 'SETSPEED XXX MPH / KM/H' message in the message center. The indicator is illuminated in an amber color for a 3 second indicator check when the ignition is switched on.

7. Anti-lock Braking System (ABS) Warning Indicator

The **ABS** warning indicator is controlled by the **ABS** module. If a fault in the **ABS** system is detected by the **ABS** module, the module issues a high speed **CAN** message to the instrument cluster to illuminate the **ABS** warning indicator in an amber color and display the message 'ABS FAULT' in the instrument cluster. The indicator is illuminated in an amber color for a 3 second indicator check when the ignition is switched on. If a fault is present when the ignition is on, the bulb will remain illuminated after the 3 second indicator check period.

- **NOTE:** The 'ABS FAULT' message is not displayed in NAS markets).

- **NOTE:** If both the **ABS** warning indicator and the brake warning indicator illuminate simultaneously, a major fault in the brake system will have occurred.

On NAS vehicles, the [ABS](#) warning indicator is also used for parking brake operation. The NAS warning indicator does not have 'ABS' on the icon and will function as described previously for the parking brake operation of the brake warning indicator.

8. Engine Malfunction Indicator Lamp (MIL)

The MIL warning indicator is controlled by the [ECM](#) and illuminated by the instrument cluster on receipt of a message on the high speed [CAN](#) bus from the [ECM](#). The indicator is illuminated in an amber color for a 3 second indicator check when the ignition is switched on.

If the MIL remains illuminated after the engine is started or illuminates when driving, a fault is present and must be investigated at the earliest opportunity. Illumination of the MIL warning indicator alerts the driver to an [OBD \(on-board diagnostic\)](#) fault which will cause excessive emissions output. This may relate to either an engine management system fault or a transmission.

9. Tire Pressure Monitoring System (TPMS) Warning Indicator

The TPMS warning indicator is illuminated by the instrument cluster on receipt of a medium speed [CAN](#) message from the TPMS module. The indicator is illuminated in an amber color for a 3 second indicator check when the ignition is switched on.

If the indicator illuminates and is accompanied by the message 'TYRE PRESSURE SYSTEM FAULT' in the message center, then a TPMS fault has occurred. If the indicator illuminates and accompanied by a different message, then a low tire pressure has been detected, a spare wheel has been fitted or a TPMS sensor has failed.

10. Airbag Warning Indicator

The airbag warning indicator is controlled by the instrument cluster. The indicator is illuminated in an amber color for the 3 second indicator check when the ignition is switched on. The indicator remains illuminated after the 3 second period has expired until the instrument cluster receives a turn off message on the high speed [CAN](#) bus from the [RCM \(restraints control module\)](#).

11. Front Fog Lamp Indicator

The green colored front fog lamp indicator is controlled by the [CJB](#) and illuminated by the instrument cluster on receipt of a front fog lamp on message on the medium speed [CAN](#) bus from the [CJB](#). The indicator is illuminated for as long as the front fog lamps are active. The front fog lamp indicator is not subject to the 3 second indicator check when the ignition is switched on.

12. Dynamic Stability Control (DSC) Indicator

The DSC warning lamp is controlled by the [ABS](#) module and illuminated by the instrument cluster in response to messages received on the high speed [CAN](#) bus. The indicator is illuminated in an amber color for the 3 second indicator check when the ignition is switched on. The DSC warning indicator, are permanently illuminated in an amber color if the instrument cluster receives a high speed [CAN](#) message from the [ABS](#) module relating to one of the following faults:

- Traction control fault
- Yaw control fault
- Engine drag torque control fault
- Panic Brake Assist (PBA) fault
- Signal missing relating to either traction control active, yaw control active or DSC switch input.

The above faults will also generate an applicable DSC and ABS warning message in the message center. The DSC warning indicator will flash at 2 Hz for if the traction control or yaw control is active when the DSC system is enabled. If the DSC system is switched off, the warning indicator will be permanently illuminated until the DSC system is subsequently re-activated.

13. Safety Belt Warning Indicator

The safety belt warning indicator operates for both the driver and passenger safety belts. The warning indicator is controlled by the [RCM](#) and illuminated by the instrument cluster on receipt of high speed [CAN](#) bus messages. The safety belt warning indicator is not subject to the 3 second indicator check when the ignition is switched on.

The operation of the passenger seat buckle switch is as described below with the exception that the instrument cluster must receive a hardwired signal from the belt minder control module to indicate that a passenger is occupying the seat.

The safety belt warning indicator is subject to a timer. The warning indicator is activated when the following conditions exist:

- Ignition is switched on
- One of the front seat belts is unbuckled
- USA market only - 75 seconds has elapsed after ignition on mode is selected
- Vehicle is not in reverse gear
- Vehicle speed is more than 8 km/h (5 mph).

Once the above parameters are met, the instrument cluster flashes the warning indicator at 2 Hz for 10 seconds accompanied by a simultaneous chime. After 10 seconds the chime ceases and the warning indicator is permanently illuminated for 20 seconds. This sequence is repeated every 30 seconds until one of the following events occurs:

- 300 seconds has elapsed
- The safety belt of the occupied front seats is fastened
- The ignition is switched to off mode
- The vehicle speed decreases to below 5 km/h (3 mph).

• **NOTE:** On USA market vehicles, the warning indicator is not permanently illuminated.

The safety belt minder function cannot be disabled. The seat belt minder function can be disabled. Refer to: [Safety Belt System](#) (501-20A Safety Belt System, Description and Operation).

14. Side Lamp Indicator

The instrument cluster controls the green colored side lamp indicator on receipt of a side lamp status message on the medium speed [CAN](#) bus from the [CJB](#) and the auxiliary junction box. The lighting switch on the [LH](#) steering column multifunction switch is connected to the instrument cluster. Selections using this switch are detected by the cluster which requests the side or headlamp operation via a message to the [CJB](#) and the [RJB](#). The [CJB](#) and the [RJB](#) responds with a side lamp active message and the cluster illuminates the side lamp indicator. The side lamp indicator is not subject to the 3 second indicator check when the ignition is switched on.

15. High Beam Indicator

The instrument cluster controls the blue colored high beam indicator on receipt of a high beam status message on the medium speed [CAN](#) bus from the [CJB](#). The lighting switch on the [LH](#) steering column multifunction switch is connected to the instrument cluster. High beam or flash selections using this switch are detected by the cluster which requests the light operation via a [CAN](#) message to the [CJB](#). The [CJB](#) responds with a high beam active message and the cluster illuminates the high beam indicator. The high beam indicator is not subject to the 3 second indicator check when the ignition is switched on.

16. Rear Fog Lamp Indicator

The amber colored rear fog lamp indicator is controlled by the auxiliary junction box and illuminated by the instrument cluster on receipt of a rear fog lamp on message on the medium speed [CAN](#) bus from the [RJB](#). The indicator is illuminated for as long as the rear fog lamps are active. The rear fog lamp indicator is not subject to the 3 second indicator check when the ignition is switched on.

SPEEDOMETER

The speedometer is driven by high speed [CAN](#) signals transmitted by the [ABS](#) module. The wheel speeds are measured by sensors reading the rotational speed of the rear wheels from toothed targets on the hubs. An average of the two wheel speeds are passed from the sensors to the [ABS](#) module in the form of pulsed signals. The [ABS](#) module converts these signals into a speed output on the high speed [CAN](#) to the instrument cluster. The same speed outputs from the wheel speed sensors are also used to calculate the distance the vehicle has travelled.

TACHOMETER

The tachometer is driven by an engine speed signal transmitted on the high speed [CAN](#) from the [ECM](#). The signal is derived from the [CKP \(crankshaft position\)](#) sensor. The signal is received by the instrument cluster microprocessor and the output from the microprocessor drives the tachometer.

FUEL GAGE

The fuel gage is controlled by [CAN](#) messages from the [RJB](#). The [RJB](#) reads the values output by the fuel level sensors every 131 ms and transmits a fuel tank contents value, corrected for battery voltage, in a [CAN](#) message to the instrument cluster. A fuel pump symbol is displayed to the left of the linear gage. An arrow above the symbol shows the driver on which side of the vehicle the fuel filler cap is located. Above the linear fuel gage, is a [LCD \(liquid crystal display\)](#) area which displays odometer and trip readouts. When a trip computer function is selected, these are replaced by a trip computer display for the trip function selected.

LIQUID CRYSTAL DISPLAY

In the area above and below the message center is a [LCD](#) display. The area below the message center displays a linear fuel gage, odometer, trip distance and trip computer readouts. The trip distance and trip computer information is derived from information supplied on the high speed [CAN](#) bus to the instrument cluster from the [ABS](#) module and the [ECM](#).

The area above the message center displays the transmission gear position information and speed control related information. The transmission information is supplied on the high speed [CAN](#) bus from the [TCM \(transmission control module\)](#).

- NOTE: There is no engine coolant temperature gage displayed. If the engine coolant temperature increases to above a predetermined threshold, a warning message is displayed in the message center. The message is sent from the [ECM](#) in a high speed [CAN](#) message to the instrument cluster.

TRANSMISSION GEAR SELECTION POSITION

The gear position display shows JaguarDrive selector position or selected gear when using the Jaguar Sequential Shift. The gear selector module transmits a [CAN](#) message to the instrument cluster for gear selector lever position. The module also outputs a 'not in park' signal to the instrument cluster. The [TCM](#) transmits a high speed [CAN](#) message to the instrument cluster with data containing the selected gear when in Jaguar Sequential Shift mode.

13	High beam indicator
14	Seat belt warning indicator
15	Side lamp indicator
16	Message center
17	Automatic Speed Limiter (ASL) indicator
18	Forward alert indicator
19	Brake warning indicator (NAS)
20	Brake warning indicator (ROW)
21	LH turn signal indicator

The warning indicators are located in various positions in the instrument cluster. The indicators can be split into two groups; instrument cluster controlled and externally controlled.

Instrument cluster controlled warning indicators are dependent on software logic within the instrument cluster for activation. The cluster software controls the indicator illumination check at ignition on (power mode 6).

Externally controlled indicators are supplied with current from another vehicle system control module or illuminated by the instrument cluster software on receipt of a bus message from another vehicle sub-system. The indicator illumination check at ignition on (powermode 6) is also controlled by the sub-system module for these indicators.

MESSAGE CENTER

The message center is a [LCD](#) located in a central position in the cluster. The message center displays system status information.

Refer to: [Information and Message Center](#) (413-08 Information and Message Center, Description and Operation).

ANALOGUE GAGES

Speedometer

The analogue speedometer is located on the [LH](#) side of the instrument cluster and is available in 4 market variants:

- Major scale Miles Per Hour (MPH), minor scale kilometers per hour (km/h) (ROW)
- Major scale MPH, minor scale km/h (NAS)
- Major scale km/h, minor scale MPH
- Major scale km/h only.

Tachometer

The analogue tachometer is located on the [RH](#) side of the instrument cluster. The tachometer has different Revolutions Per Minute (RPM) scales depending on the engine variant fitted to the vehicle as follows:

- 4.2L V8 Supercharged 7000 RPM
- 4.2L V8 Naturally aspirated 8000 RPM
- 3.0L V6 Naturally aspirated 8000 RPM
- 2.7 V6 Diesel 6000 RPM.

ELECTRONIC GAGES

Fuel Gage

The linear fuel gage has a colored bar which moves left or right depending on the tank contents. As the bar moves to the left the fuel tank contents displayed is decreasing. A warning message is displayed in the message center when the fuel tank contents fall to below the reserve level.

Transmission Gear Position Display

The gear position display shows the JaguarDrive selector position or the selected gear when using the Jaguar Sequential Shift.

The applicable drive letter is highlighted to show that a selection has been made using the JaguarDrive selector.

When Jaguar Sequential Shift is selected, the letters change to numbers; 1 - 6, and the selected gear is highlighted to emphasize the selection to the driver.

Instrument Cluster - Instrument Cluster

Diagnosis and Testing

Principles of Operation

For a detailed description of the Instrument Cluster, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (413-01 Instrument Cluster)

[Instrument Cluster](#) (Description and Operation),
[Instrument Cluster](#) (Description and Operation),
 Instrument Cluster (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Fluid level(s) ● Accessory installations 	<ul style="list-style-type: none"> ● Fuse(s) ● Wiring harness ● Electrical connector(s) ● Instrument cluster ● Central Junction Box (CJB) ● Engine Junction Box (EJB) ● Driver Door Module (DDM) ● Engine Control Module (ECM)

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart.

Symptom Chart

The instrument cluster contains a self-diagnostic mode known as engineering test mode (ETM). This can be used to show the status of the instrument cluster inputs as well as a number of other useful features.

When in the ETM, the Message Centre displays internal data that can be cycled through. All functions except the message centre display will continue to operate normally unless otherwise noted.

This document is to be used in conjunction with the instrument cluster ETM (see relevant section within this document) and the Integrated Diagnostic System (IDS) facility; this does not supersede or replace the IDS facility.

Go directly to the 'Area of Concern/Symptom' that indicates the customer concern(s) and perform the actions described within the relevant section(s):

Area of Concern/Symptom	Diagnostic Ref. No.	Actions	Notes
Warning lights	A-1	Perform instrument cluster Self-Diagnostic Mode/ETM test 3.	When this test is ended the warning lamps currently required to be 'ON' will remain illuminated.
Multiple warning lights 'ON'	B-1	Check with IDS for DTCs related to identified vehicle system(s).	.
.	B-2	Check instrument cluster battery and ignition wiring - refer to circuit diagrams.	Specifically check continuity of Standard Corporate Protocol (SCP) and Controller Area Network (CAN) lines.
.	B-3	Check instrument cluster grounds.	.
.	B-4	Check fuses in battery junction box.	.
.	B-5	Check for harness traps in fascia.	.
.	B-6	Perform instrument cluster Self-Diagnostic Mode/ETM test 3.	Frost/ice warning illuminated in mixed red and amber; therefore colour differs from other warning lamps. When this test is ended, warning lamps currently required to be 'ON' will remain illuminated.
.	B-7	Check for open circuit/shorts in wiring to related warning lamp trigger (module, sensor, switch).	.
Specific warning lamp 'ON'	C-1	Check with IDS for DTCs related to identified vehicle system.	.
.	C-2	Check for open circuit/shorts in wiring related to warning lamp circuit (module, sensor, switch) where appropriate.	.

Area of Concern/Symptom	Diagnostic Ref. No.	Actions	Notes
.	C-3	Perform cluster Self-Diagnostic Mode/ETM test 3.	Frost/ice warning illuminated in mixed red and amber; therefore colour differs from other warning lamps. When this test is ended, warning lamps currently required to be 'ON' will remain illuminated.
.	C-4	Check the specific vehicle system indicated by the warning lamp illuminated?	What is the warning lamp telling me? Does this check out with the DTC logged by the system indicating the fault?
Fuel gauge operation	D-1	Perform Self-Diagnostic Mode/ETM test 21 to establish if fuel level input to cluster is out of range or invalid.	0 - 9 = short circuit; gauge will show empty. 10 - 254 = normal range. 255 = open circuit; gauge will show empty. --- = missing signal; gauge will show empty.
.	D-2	Check gauge function versus Self-Diagnostic Mode/ETM test 21.	0 = empty, 254 = full. 255 = invalid; gauge will show empty.
.	D-3	Check for open circuit/shorts in wiring between the Fuel Delivery Module, Jet Pump Module and Rear Electronic Module (REM).	
Fuel gauge reading	E-1	Check gauge position versus Self-Diagnostic Mode/ETM test 21.	0 = empty to 254 = full (255 invalid; gauge will show empty). Other values percentage of above range e.g. 127 = half.
.	E-2	Calculate percentage fuel level from figure obtained from Self-Diagnostic Mode/ETM test 21 and compare to IDS vehicle fuel percentage test.	Self-Diagnostic Mode fuel level percentage can be calculated as follows: Value from Self-Diagnostic Mode test 26 ÷ 254 x 100 = % shown on gauge.
.	E-3	Monitor value of Self-Diagnostic Mode test/ETM test 21 (during test drive) to establish if input drops out of range.	0 - 9 = short circuit; gauge will show empty. 10 - 254 = normal range. 255 = open circuit; gauge will show empty. --- = missing signal; gauge will show empty.
.	E-4	Monitor 'FUEL LEVEL' in IDS data logger (during test drive) to correlate gauge position to vehicle reported fuel level.	Gauge function is damped so will not follow rapidly changing Fuel Delivery Module values.
Speedometer operation	H-1	Monitor Self-Diagnostic Mode/ETM test 19 (during test drive) check to establish if vehicle speed input to cluster is out of range or invalid.	Display speed input in 1/10 mile/h, no decimal point shown, and is compensated for tire size etc. Displays ---- or INV if message is not received or if received data is invalid.
Speedometer reading	I-1	During test drive compare speedometer position to Self-Diagnostic Mode/ETM test 19, displayed value.	Self-Diagnostic Mode displayed speed figure will be approx 3% higher than speed indicated by speedometer. Allowed tolerance - minus nothing/+ 10% + 2.5 mile/h.
.	I-2	Monitor Self-Diagnostic Mode/ETM test 19 (during test drive) to establish if vehicle speed input to cluster drops out of range or is invalid.	Displays ---- if message is not received or if received data is invalid for two seconds or more.
.	I-3	Check that installed wheels and tires are standard Jaguar fitment. Confirm wheel size in IDS, 'ADD REMOVE ACCESSORY' section.	Non standard wheels and tires may lead to speed indication inaccuracies. Incorrectly set wheel size will result in speed indication inaccuracies. Trip and odometer distance accumulation will also be incorrect.
Tachometer operation	J-1	Perform Self-Diagnostic Mode/ETM test 20 to establish if vehicle rpm input to cluster out of range or invalid.	Displays ---- or INV if message is not received or if received data is invalid.
Tachometer reading	K-1	Check tachometer position versus Self-Diagnostic Mode/ETM test 20, displayed value.	Tachometer accuracy +/- 100 rpm.
.	K-2	Monitor 'ENGINE RPM' in IDS data logger at constant engine rpm to compare tachometer indicated engine rpm to engine rpm reported by Engine Control Module (ECM).	Tachometer accuracy +/- 100 rpm.
.	K-3	Monitor Self-Diagnostic Mode test/ETM test 20, (during test drive) to establish if input to cluster drops out of range or is invalid.	Displays ---- or INV if message is not received or if received data is invalid.
Gauge judder	L-1	Perform Self-Diagnostic Mode test/ETM test 2, to prove out smooth gauge operation.	
Gauge noise	M-1	Perform vehicle road test. Gauges should not be audible during operation in drive cycle.	
.	M-2	Benchmark noise against non-complaint vehicle.	
Trip (fuel) computer	N-1	Check for consistent display (during test drive) of valid 'Rolling Odometer' count in Self-Diagnostic Mode/ETM test 24.	Displays ----, INV or 255 if message is not received, or if received data is invalid.
.	N-2	Check that installed wheels and tires are standard Jaguar fit. Confirm fitted wheel size in IDS, 'ADD REMOVE ACCESSORY' section.	Non standard wheels and tires or incorrectly set wheel size may lead to Odometer increment inaccuracies. This will impact the distance accumulators, which in turn affects the rolling average, fuel economy and range

Area of Concern/Symptom	Diagnostic Ref. No.	Actions	Notes
			values. Trip distance accumulation will also be incorrect.
	N-3	Consider noting odometer value and resetting fuel computer system. Advise customer to conduct brim-to-brim fuel tank test. Use collected information to determine if system accurate.	
Column adjust	O-1	Check with IDS for DTCs related to powered column system.	
	O-2	Check cluster battery supply voltage and ground resistance. Check for loose connections.	
	O-3	Check power column motors supply voltage.	
	O-4	Check power column switch for physical damage.	
Passive Anti-Theft System (PATS) indicator	P-1	Check for three second prove out when vehicle start button is pressed.	
	P-2	Check for loose connections/wiring continuity.	
	P-3	Check ignition switch for physical damage.	
Cluster illumination	Q-1	Check for loose connections/wiring continuity.	
	Q-2	Check dimmer switch operation.	
Cluster backlight operation	R-1	Is the backlight on other components inoperative.	
	R-2	Check dimmer switch operation.	
	R-3	Check for loose connections/wiring continuity.	
Chime/tone operation	S-1	Check vehicle configuration.	
	S-2	Utilize lights ON, ignition OFF, door open warning to verify chime operation.	
	S-3	Check appropriate sensing circuit.	
Continuous chime/tone	T-1	Check appropriate sensing circuit.	
Unexpected chime operation	U-1	Check vehicle configuration.	
Message centre display illumination	V-1	Is the backlight 'ON' and other components dim?	
	V-2	Does the lighting level of other components change when dimmer adjusted?	
Message centre display issue	W-1	Perform Self-Diagnostic Mode test/ETM tests 5 to 9, to prove out LCD display function.	
Message centre missing lines	X-1	Perform Self-Diagnostic Mode test/ETM tests 5 to 9, to prove out LCD display function.	
Message centre incorrect message	Y-1	What is the message?	
	Y-2	Check for open circuit/shorts in wiring to related warning light trigger (module, sensor, switch).	
Cluster/connectivity	Z-1	Check cluster battery and ignition wiring.	
	Z-2	Check cluster grounds.	
	Z-3	Disconnect/reconnect cluster.	
	Z-4	Attempt to enter Self-Diagnostic Mode/ETM to prove cluster response to inputs.	
No crank	AA-1	Check with IDS for presence of related DTCs.	
	AA-2	Is there a Passive Anti-Theft System (PATS) flash code?	
	AA-3	Does the vehicle crank with the other passive key?	
	AA-4	Ensure only one key is in the vehicle, try both keys in the Starter Control Unit (SCU).	If this test starts the vehicle this tends to indicate an issue with the keyless vehicle module.
	AA-5	Tried new key?	
	AA-6	Check battery voltage.	
	AA-7	Diagnose non-start condition with IDS.	
	AA-8	Attempt PATS key erase and re-learn.	Ensure keys are erased from current cluster if replacing cluster.
Crank but no-start	AB-1	Diagnose non-start condition with IDS.	Not usually caused by cluster issue.
Incorrect configuration	AC-1	Attempt to configure cluster.	

Area of Concern/Symptom	Diagnostic Ref. No.	Actions	Notes
	AC-2	Ensure battery voltage is maintained above 12.5 volts if cluster re-configured.	

1. If the cause is not visually evident, verify the symptom and refer to the Self-Diagnostic Mode

Self-Diagnostic Mode

To place the cluster in engineering test mode (ETM) carry out the following steps

1. Press and hold the stalk trip cycle button, for more than five seconds but less than eight seconds, whilst briefly pressing the vehicle START button. There is no initial display indication that the instrument cluster has entered ETM. If ETM has successfully been entered then 'ENGINEERING TEST MODE' will be displayed in the Message Centre when the stalk trip button is released .
- 2.To navigate forward through the instrument cluster Self-Diagnostic Mode tests, press the stalk trip cycle button.
3. Each push of the stalk trip cycle button will advance one step through the ETM sequence. It is not possible to move backward through the test sequence.
- 4.To exit the Self-Diagnostic Mode press and hold the stalk trip cycle button for more than three seconds.
- 5.The Self-Diagnostic Mode is also deactivated when the ignition switch is turned to the 'OFF' position or low battery voltage is detected.
- 6.If the Self-Diagnostic Mode cannot be accessed repeat the above paying particular care to the sequence timing.
- 7.The ETM text is not language configurable and will be displayed in English.

ETM Test/no.	Message Center Display	Gauge/Indicator/Display Tested.	Range	Description
1 - Self-diagnostic entry.	ENGINEERING TEST MODE.		Not Applicable (N/A).	Establishes Self - Diagnostic mode.
2 - Gauge sweep.	GAUGE SWEEP.	Tachometer and speedometer. Gauges display current values after test.	(N/A).	All gauges go through a full up and down pointer sweep smoothness check.
3- Warning lamp LED's.	TELL TALE TEST.	All internally controlled lamps/LED's regardless of software configuration.	(N/A).	Illuminates all the LED warning indicators that are controlled by the instrument cluster. When this test is exited current vehicle warning lamps will remain illuminated.
4 - Version information.	PROGRAM VERSION. <ul style="list-style-type: none"> ● ROM: XXXX ● NVM: XXXX ● REV: XXXX ● DATE: XXXX 	Software Read only memory (ROM) and Non volatile memory (NVM) version and date.	(N/A).	Display's the instrument cluster ROM and NVM level version and date or indication of ROM checksum fault.
5 - Message Center display.	LCD display in WHITE.	Message center LCD display.	(N/A).	Activates all pixels of LCD display in White.
6 - Message Center display.	LCD display in DARK GREY.	Message center LCD display.	(N/A).	Activates all pixels of LCD display in Dark Grey.
7 - Message Center display.	LCD display in LIGHT GREY.	Message center LCD display.	(N/A).	Activates all pixels of LCD display in Light Grey.
8 - Message Center display.	LCD display in four bands black to white, top to bottom.	Message center LCD display.	(N/A).	Activates all pixels of LCD in four bands from black to white, from top to bottom.
9 - Message Center display.	LCD display in four bands dark to light left to right.	Message center LCD display.	(N/A).	Activates all pixels of LCD in four bands from dark to light, from left to right.
10 - Digital I/O.	DIGITAL I/O. <ul style="list-style-type: none"> ● A: XXXX E: XXXX ● B: XXXX F: XXXX ● C: XXXX G: XXXX ● D: XXXX H: XXXX 	Cluster configuration settings.	(N/A).	Display Hex coding of cluster configuration settings ports A to H. Not defined for diagnostic purpose.

31- Back to test 2.	GAUGE SWEEP.	Tachometer and speedometer.	N/A.	Repeats display cycle from test 2.

1. 1. If the cause is not visually evident, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• **NOTE:** If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• **NOTE:** Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B100811	Wiper Mode Switch	<ul style="list-style-type: none"> Master wiper switch circuit - short to ground 	Refer to the electrical circuit diagrams and check master wiper switch circuit for short to ground

Instrument Cluster - Instrument Cluster

Removal and Installation

Removal

 **CAUTION:** If a new instrument cluster is to be installed, the diagnostic tool must be connected prior to removal, the data must then be downloaded from it and the keys (remote control handsets) set into default mode. Failure to follow this instruction will result in permanent damage to the keys.

- NOTE: If a new instrument cluster is to be installed, make sure that all keys (remote control handsets) are present.
- NOTE: Removal steps in this procedure may contain installation details.

1. Fully extend and lower the steering column for access.
2. Refer to: [Battery Disconnect and Connect](#) (414-01 Battery, Mounting and Cables, General Procedures).

3.

4.

5.

E95491

6.

E96003

7.

8.  CAUTION: Take extra care not to damage the instrument cluster face.

Installation

1. To install, reverse the removal procedure.
2. Configure the instrument cluster and ignition keys using the diagnostic tool.

Information and Message Center - Information and Message Center - Component Location

Description and Operation

COMPONENT LOCATION

E93390

ItemDescription

- 1 Message center

Information and Message Center - Information and Message Center -

Overview

Description and Operation

OVERVIEW

The message center is a [LCD \(liquid crystal display\)](#) located in a central position in the instrument cluster. The message center receives [CAN \(controller area network\)](#) bus, [LIN \(local interconnect network\)](#) bus, and hardwired signals from other vehicle system control modules to display current vehicle status information. Depending on message importance, the message center will be backlit in white, amber or red.

The message center will display:

- Fuel level
- Trip computer information
- Gear selected
- Speed control information
- Vehicle map
- Clock
- Turn by turn satellite navigation
- Voice control text
- JaguarDrive Control system messages.

Operation of the message center is controlled by software within the instrument cluster.
Refer to: [Instrument Cluster](#) (413-01 Instrument Cluster, Description and Operation).

Information and Message Center - Information and Message Center - System Operation and Component Description

Description and Operation

System Operation

SERVICE INTERVAL INDICATOR - DIESEL MODELS ONLY

If the vehicle is within 3,200 kilometers (1,988 miles) of a service, the message center will display 'SERVICE REQUIRED IN XXXX km or MILES'. The display reduces the 'service required in' readout by increments every 50 kilometers (30 miles). If this distance drops below 1 km (0.6 miles), the message center will display 'SERVICE REQUIRED'.

These messages are displayed every time the vehicle enters power mode 6, for 4 seconds after the instrument cluster bulb check routine has finished.

• **NOTE:** The message center will display distance to next service in miles on an instrument cluster fitted with a Miles Per Hour (MPH) speedometer unless the driver has changed the display units on the Touch Screen Display (TSD).

Reset Procedure

To re-set the service interval indicator, the following process switch presses must each be carried out within 3 seconds:

- With the vehicle in power mode 0, (ignition off) press and hold the rear fog lamp switch
- Allow the vehicle to enter power mode 6 (Press the start button without a foot on the brake)
- Immediately release the rear fog lamp switch
- Press and hold the trip computer cycle switch
- Press and hold the rear fog lamp switch
- Continue to hold the trip computer and rear fog lamp switches
- If the process has been successful, the message center will display 'RESETTING SERVICE MODE' and then display 'SERVICE MODE RESET' after 10 seconds
- Release both switches and return the vehicle ignition to off, power mode 0.

Component Description

MESSAGE CENTER

The message center [LCD \(liquid crystal display\)](#) display has a viewable area of 126 pixels horizontal and 174 pixels vertical. It is divided into six information display zones as follows, starting from the top:

- Set speed
- Transmission position
- Warning /message display
- JaguarDrive Optimization icon
- Odometer/Trip computer information
- Fuel level.

The message center is active at all times when the ignition is on and can also be active when the ignition is off, dependant on the information to be displayed. The message center [LCD](#) illumination is controlled by the sun load light sensor located on the instrument panel. In bright conditions, the illumination is set to maximum brightness. As the ambient light levels drop, the illumination dims. When the lights are switched on or activated by the 'AUTO' function, the illumination operates in the same way until a defined ambient light threshold is reached, at this point the setting of the panel illumination dimmer in the auxiliary light switch will control the brightness.

If more than one message is active, each message is displayed for 4 seconds in the order of priority. Once all messages have been displayed, they are again displayed in turn for 2 seconds each. Warning messages can be displayed when the ignition is in accessory power mode 4 which is the initial ignition state when a door is opened.

Message Priority

Messages are assigned priorities which are defined by the effect on driving safety and functional ability of the vehicle. When new messages are displayed they may be accompanied by a chime from the instrument cluster sounder. A new message will be displayed immediately, providing the currently displayed message (if there is one) has been displayed for at least 4 seconds. A warning indicator will be activated simultaneously with the message being displayed. If more than one fault warning message is being displayed, the messages will cycle, in priority order, with each message being displayed for 2 seconds.

INFORMATION DISPLAY

The transmission display is located in the upper section of the [LCD](#). The transmission position information is sent from the [TCM \(transmission control module\)](#) in a high speed [CAN \(controller area network\)](#) message to the instrument cluster. The transmission has three modes of operation:

- Conventional automatic operation (JaguarDrive selector in 'D' position)
- Sport automatic operation (JaguarDrive selector in 'S' position)
- Manual gear operation - Jaguar Sequential Shift.

The following table shows the JaguarDrive selector position and the highlighted indication displayed in the transmission display.

JaguarDrive Selector Position	Transmission Display
(P) Park	P
(R) Reverse	R

Jaguar Drive Selector Position	Transmission Display
(N) Neutral	N
(D) Drive	D
(S) Sport	S

The following table shows the Jaguar Sequential Shift display. Selections are made using the steering wheel mounted paddle switches.

Jaguar Sequential Shift Gear Selection	Transmission Display
First	1
Second	2
Third	3
Fourth	4
Fifth	5
Sixth	6

The transmission may inhibit a requested up or down shift if the requested gear is outside the normal engine speed operating range. If this occurs, the transmission display will briefly display the gear requested by the driver but will then change to display the actual gear selection.

Speed Control and Set Speed Displays

The following table shows the possible messages which can be displayed, other visual or audible warnings and a description of the message.

Message	Other Warnings	Reason	Action
OVERLIMIT XXX MPH (km/h)	<ul style="list-style-type: none"> Amber ASL warning indicator illuminated at +4.8 km/h (+3 mph) above limit Amber ASL warning indicator flashing at +24 km/h (+15 mph) above limit Amber ASL warning indicator flashing and chime emitted at +24 km/h (+15 mph) for a certain time period 	Displayed when vehicle speed exceeds the ASL set speed	Reduce vehicle speed to ASL set limit
LIMITER CANCELLED	None	Displayed for 4 seconds when driver deselects ASL	None
LIMITER SET XXX MPH (km/h)	None	Displays new speed setting for the ASL	None
LIMITER STANDBY	None	Displayed when ASL is activated and speed control is selected	None
LIMITER NOT AVAILABLE	None	Displayed when ECM (engine control module) has detected a fault	Use an approved Jaguar Diagnostic System to diagnose fault
TOO FAST TO RESUME	None	Displayed when 'Resume' switch is pressed but vehicle speed is 30 km/h (18 mph) above the set speed.	Reduce vehicle speed to set speed then press 'Resume' switch.
CRUISE CANCELLED	None	Driver has cancelled speed control or the brake pedal has been pressed.	None
CRUISE OVERRIDE	None	Driver has pressed the accelerator pedal, overriding the speed control system. Message will go off when accelerator pedal is released and speed control is active.	WARNING: Adaptive cruise braking will be disabled when this message is displayed.
GAP 1 / 2 / 3 / 4	None	Displays the current set or default adaptive speed control distance. Displayed along with a vehicle graphic in the LCD . Chevrons (>) denote gap figure selected.	If required, adjust distance using the steering wheel switches.
SETSPEED XXX MPH (km/h)	None	Displays the new speed input for the speed control	None
DRIVER INTERVENE	None	Immediate action required by the driver to apply the brakes if required.	<ul style="list-style-type: none"> Apply brakes if required. May also be displayed if speed control system loses CAN messages when active.
CRUISE NOT AVAILABLE	None	Speed control cannot be engaged.	A fault has occurred in the speed control system. Diagnose fault using an approved Jaguar Diagnostic System.
RADAR SENSOR BLOCKED	None	The adaptive speed control radar sensor has become dirty or obstructed.	Remove obstruction or clean the radar sensor.
FORWARD ALERT OFF	None	Forward alert has been switched off. No warning will be given for objects in the vehicles forward direction.	None

Message	Other Warnings	Reason	Action
FORWARD ALERT	None	Forward alert has been switched on or the gap settings have changed.	None

Warning/Message Display

Warning and information messages are displayed in the central area of the [LCD](#). When no messages are required, an analogue clock is present on the display. The message display language can be changed by the driver using a selection menu on the Touch Screen Display (TSD). The following table shows the possible messages which can be displayed, other visual or audible warnings and a description of the message.

Message	Other Warnings	Reason	Action
DSC ON	DSC warning indicator flashes for a short time.	Displayed for a short time when the DSC switch is operated to activate the DSC system.	None
DSC OFF	DSC warning indicator illuminated.	Displayed for a short time when the DSC switch is operated to de-activate the DSC system.	None
TRAC DSC	DSC warning indicator illuminated.	Displayed for a short time when the DSC switch is operated to activate the TRAC DSC system.	None
DSC NOT AVAILABLE	DSC warning indicator illuminated.	A fault is present in the DSC system.	A fault has occurred in the DSC system. Interrogate ABS (anti-lock brake system) module for faults and diagnose fault using an approved Jaguar Diagnostic System.
BRAKE FLUID LOW	<ul style="list-style-type: none"> ● Brake warning indicator illuminated. ● Red warning triangle illuminated in LCD. 	Brake fluid level has become low and activated low level switch.	Investigate fluid loss and check brake system for leaks. Repair system as required and replenish brake fluid reservoir.
ABS FAULT	<ul style="list-style-type: none"> ● ABS warning indicator illuminated. ● Amber warning triangle illuminated in LCD. 	A fault is present in the ABS system. Braking system will operate but ABS will not be available.	A fault has occurred in the ABS system. Interrogate ABS module for faults and diagnose fault using an approved Jaguar Diagnostic System.
BRAKE ASSIST FAULT	Amber warning triangle illuminated in LCD .	A fault is present in the braking system preventing brake assist operation. Braking system will operate but brake assist will not be available and increased effort on the brake pedal may be required.	A fault has occurred in the brake assist system. Interrogate ABS module for faults and diagnose fault using an approved Jaguar Diagnostic System.
EBD FAULT	Red warning triangle illuminated in LCD .	A fault is present in the braking system preventing EBD operation. Braking system will operate but EBD will not be available.	A fault has occurred in the EBD system. Interrogate ABS module for faults and diagnose fault using an approved Jaguar Diagnostic System.
CATS SYSTEM FAULT	Amber warning triangle illuminated in LCD .	A fault is present in the Computer Active Technology Suspension (CATS). Suspension will default to the 'hard' setting.	A fault has occurred in the CATS system. Interrogate the CATS module for faults and diagnose using an approved Jaguar Diagnostic System.
PARK BRAKE APPLIED	None	Parking brake has been applied when the vehicle moving at a speed 5 km/h (3 mph) or above.	None
PARK BRAKE FAULT	<ul style="list-style-type: none"> ● Brake warning indicator illuminated. ● Red warning triangle illuminated in LCD. 	A fault is present in the parking brake system.	A fault has occurred in the parking brake system. Interrogate the parking brake module for faults and diagnose using an approved Jaguar Diagnostic System.
APPLY FOOT AND PARK BRAKE	Amber warning triangle illuminated in LCD .	The battery has been disconnected or power supply interrupted to the parking brake module.	Apply foot brake and parking brake to reset the parking brake module.
CANNOT APPLY PARK BRAKE	<ul style="list-style-type: none"> ● Brake warning indicator flashing. ● Red warning triangle illuminated in LCD. ● NOTE: In certain markets the brake warning indicator does not flash. 	A fault is present in the parking brake system and the parking brake cannot be applied.	A fault has occurred in the parking brake system. Interrogate the parking brake module for faults and diagnose using an approved Jaguar Diagnostic System.
Oil Service Display OIL SERVICE PRESSURE The odometer displays the (M) warning which wheel speed signals from the ABS module. The odometer can show 6 characters and distances up to 999,999 miles or kilometers. stored in a EEPROM (electrically programmable read only memory) and the RAM (random access memory) . This ensures that the total distance is not lost if the battery is disconnected.	<ul style="list-style-type: none"> ● Tire Pressure Monitoring System (TPMS) warning indicator illuminated. ● Vehicle graphic illuminated. 	A tire pressure has decreased to below the warning threshold.	Check tires for punctures and re-inflate to correct pressures. Calculated by the instrument cluster using

The odometer value is passed to other vehicle system modules on the medium speed and high speed [CAN](#) bus. This is used to record the total vehicle mileage for diagnostic purposes and when storing [DTC \(diagnostic trouble code\)](#)'s.

Trip computer Information Display

The instrument cluster contains software which controls the trip computer. The computer allows the driver to access information for current fuel usage, current journey length, average speed and estimated vehicle range of fuel remaining.

The information is calculated from [CAN](#) messages from other vehicle systems, for example wheel speed signals from the [ABS](#) module and fuel injector operating data from the [ECM](#).

A 'Trip' button is located on the end of the [LH \(left-hand\)](#) multifunction switch and allows the driver to access, in sequence, the available trip information by repeatedly pressing the button. The trip information is displayed in the following order:

- Trip distance – The trip distance since the last reset is displayed
- Average speed – The average speed since the last reset is displayed
- Average fuel consumption – The average fuel consumption since the last reset is displayed
- Range – The range is displayed showing the distance which can be travelled until the fuel gage reads empty. If the range display shows dashes (-), this indicates a failure with one or both of the fuel level sensors.

The trip computer has three independent memories; A, B and Auto. Memories A and B can be set independently. The Auto memory is reset after each ignition cycle and therefore only contains information relating the current journey.

The trip information can also be accessed from the TSD located in the center console. The TSD allows the same information available with the trip button on the multifunction switch to be displayed on the TSD, with the addition of the option to reset the values in the A and B memories.

If the battery is disconnected, all trip data in memories A, B and Auto are erased.

Fuel Level Display

The fuel level display is a linear [LCD](#) display to show the usable fuel tank contents. The level display is active at all times when the ignition is on. Low fuel level is displayed as a LOW FUEL LEVEL message and an amber warning triangle in the message center.

The fuel level is obtained by fuel level sensors in the fuel tank. These are monitored by the [RJB](#) software and their output resistance values, corresponding fuel quantity, are transmitted to the instrument cluster on the medium speed [CAN](#) bus. The instrument cluster uses the two level sensor signals to calculate the fuel tank contents. This calculation takes into account fuel movement in the tank to display a steady fuel quantity in the [LCD](#).

The fuel level information is transmitted on the medium speed and high speed [CAN](#) bus for use by other vehicle system modules.

AUDIBLE WARNINGS

The instrument cluster can generate audible warnings to alert the driver to a displayed message and change of vehicle operating condition. The audible warning is generated by a sounder located within the instrument cluster. The audible warnings can be generated for the warnings below and are listed in order of priority, with the first being the highest priority:

- Seatbelt reminder
- EPB (High Pitch)
- ACC Driver Intervene 1
- Airbag fault
- Key in ignition switch
- ASL overspeed
- ACC Driver Intervene 2
- EPB (Low Pitch)
- Vehicle armed (entry delay)
- JaguarDrive selector not in park
- Valet mode
- Lights on reminder
- Hood operation
- Passive Entry / Passive Start (PEPS)
- Memory set
- Turn signal indicators
- Seat Belt Minder.

The audible warnings can take the form of a single chime, a number of chimes or a continuous chime. The audible warnings are initiated by a CAN message request from the requesting sub-system control module or by the instrument cluster software.

Diagnosis and Testing

Principles of Operation

For a detailed description of the Blindspot Monitoring system, refer to the relevant Description and Operation sections in the workshop manual. REFER to: (413-09)

Blind Spot Monitoring System (Description and Operation),
Blind Spot Monitoring System (Description and Operation),
Blind Spot Monitoring System (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

• **NOTE:** Particular attention should be paid to the following items where DTCs may not be logged:

- Check for contamination (e.g. dirt, grime, frosting, ice) around the blindspot monitoring sensors and clear.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> • Exterior rear view mirror glass • Mud or sleet contamination around rear bumper area • Blindspot Monitoring Modules 	<ul style="list-style-type: none"> • Fuse(s) • Relay(s) • Wiring Harness • Electrical connector(s) • Blindspot Monitoring Modules

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, verify the symptom and refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
<ul style="list-style-type: none"> • The instrument cluster displays 'BSM System Fault' • DTC B11C915 is logged within the left hand Blind Spot Monitoring module • The Left Alert icon is constantly illuminated 	<ul style="list-style-type: none"> • Left driver display alert LED circuit - short to power 	Refer to the electrical circuit diagrams and check left driver display alert LED circuit for short to power

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• **NOTE:** If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• **NOTE:** Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).

• **NOTE:** When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance always take the resistance of the DMM leads into account.

• **NOTE:** Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• **NOTE:** Inspect connectors for signs of water ingress, and pins for damage and/or corrosion.

• **NOTE:** If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

• **NOTE:** When carrying out repair/diagnosis of the system, on removal of the front or rear bumper inspect the sensor

connectors to ensure they were correctly latched and check fly leads for signs of chaffing or trapped wires.

Parking Aid - Parking Aid - Overview

Description and Operation

OVERVIEW

The parking aid system provides an audible warning to the driver when any obstacles are in the path of the vehicle during a forward (if front sensors are fitted) or reversing manoeuvre. The purpose of the system is to assist the driver when parking or manoeuvring in a restricted space. It is not designed as a crash avoidance system or a replacement for visual interpretation by the driver.

All vehicles are fitted with rear parking aid sensors. Higher specification vehicles may also be fitted with front parking aid sensors.

A roof console mounted parking aid switch allows the driver to deactivate the parking aid system if operation is not required.

- **NOTE:** The switch is only fitted to vehicles with front parking aid sensors.

A parking aid camera is a standard fitment on some models and optional on others. The parking aid camera supplements the information provided by the parking aid system by providing the driver with a visual display of the area directly behind the vehicle.

System Operation

PARKING AID

The parking aid module receives and ignition power mode 6 supply from the [RJB](#).

The parking aid module is connected to the entertainment system control module by the medium speed [CAN \(controller area network\)](#) bus and the Media Orientated System Transport (MOST). The entertainment system is used by the parking aid system to provide the driver with an audible warning. If an obstacle is sensed by the rear parking aid sensors, the rear audio system speakers will sound. If an obstacle is sensed by the front parking aid sensors (if fitted), the front audio system speakers will sound.

The parking aid system operates using ultrasonic signals which are transmitted by the sensors. The reflected echo from this output is received by the sensors and used by the parking aid module to calculate the distance from an object.

When the parking aid module activates the system, the switch [LED \(light emitting diode\)](#) is illuminated to indicate that the system is operating. The parking aid module then processes signals received from the sensors to determine if there is an object within the detection range of the sensors. A parking aid screen is automatically displayed in the Touch Screen Display. If the vehicle has a parking aid camera fitted, the camera display is automatically displayed in the TSD in preference to the parking aid alert display. To view the parking aid sensor display, a single touch of the TSD screen will remove the camera image display and show the parking aid alert display.

Parking Aid Alert Display

E99384

In the combined mode, the sensors emit a series of ultrasonic impulses and then switch to receiver mode to receive the echo reflected by an obstacle within the detection range. The received echo signals are amplified and converted from an analogue signal to a digital signal by the sensor. The digital signal is passed to the parking aid module and compared with pre-programmed data stored in an [EEPROM \(electrically erasable programmable read only memory\)](#) within the module. The module receives this data via the signal line from the sensor and calculates the distance from the object using the elapsed time between the transmitted and received impulse. The duration of the impulse duration is determined by the module, with the sensor controlling the frequency of the impulse output.

In receiver mode, the sensor receives impulses that were emitted by adjacent sensors. The module uses this information to precisely determine the position and distance of the object.

If no objects are detected there are no further warning tones. If an object is detected, repeated audible tones are emitted from either the front or rear audio speakers as appropriate. The time delay between the tones decreases as the distance between the object and the vehicle decreases, until at approximately 250 mm (10 inches), the audible tone becomes continuous.

If, after the initial detection of an object, there is no decrease in distance between the object and the vehicle, the audible warning tones remain constant if the object is detected by a central sensor or stops after 3 seconds if the object is detected by a corner sensor.

The audible tones will stop if the vehicle is moved out of reverse gear. The module continues to monitor the distance and will resume the warning tones if a decrease in distance is detected.

The volume output of the parking aid audible tones can be adjusted by selecting the 'Vehicle Settings' menu and selecting 'Parking' from the menu on the TSD. The volume can be adjusted using the + or - selections on the TSD.

System operation is cancelled when the parking aid switch is pressed or the ignition is switched off. System operation is also cancelled if the vehicle travels more than 50 m (164 ft) or the vehicle forward speed exceeds 30 km/h (19 mph).

The system can detect when a trailer is connected to the vehicle by a message output on the medium speed [CAN](#) bus from the trailer module. When the parking aid module detects that a trailer is connected to the vehicle, the rear sensors are disabled to prevent constant warnings due to the close proximity of the trailer.

The parking aid module also incorporates software that compensates for the effects of frost, ice or rain on the sensors. Ice compensation occurs if the ambient temperature, received on a medium speed [CAN](#) bus message from the instrument cluster, is less than 6°C (43°F).

Distance Calculation

E99385

ItemDescription

1	600 mm (24 inches)
2	1800 mm (71 inches)
3	800 mm (31 inches)

An intermittent warning tone is emitted once the object is within the detection range for the particular sensor. When the object is 250 mm (10 inches) from the sensor, the tone changes to a continuous tone.

The maximum detection range for the front sensors is 800 mm (31 inches) for the central sensors and 600 mm (23.5 inches) for the corner sensors.

The maximum detection range for the rear sensors is 1800 mm (70 inches) for the central sensors and 600 mm (23.5 inches) for the corner sensors.

PARKING AID CAMERA

The parking aid camera receives an ignition power mode 6 power supply from the [RJB](#). It also has a [LIN \(local interconnect network\)](#) bus connection from the [RJB](#) which is not used at the moment but installed for a later enhancement of the parking aid camera.

A shielded co-axial cable connection between the camera and the Touch Screen Display (TSD) is used for the video image transmission.

The camera receives power at all times when the ignition is in power mode 6. When reverse gear is selected, the [RJB](#) transmits a reverse selected signal on the medium speed [CAN](#) bus message to the entertainment system control module. This message is transferred on the MOST to the TSD which displays the parking aid camera video input from the camera in preference to the parking aid alert screen.

If the driver does not require the camera image in the TSD, a single touch on the screen will revert the display to the parking aid alert screen. The camera view can be reselected by pressing the 'Rear Camera' softkey on the TSD.

When reverse gear is deselected, the camera image remains on the TSD for 10 seconds after the transmission has been put into drive 'D'. This is to prevent the TSD switching between screens if the vehicle is being manoeuvred into a parking space. If the vehicle forward speed exceeds 16 km/h (10 mph) within the 10 second period, the camera image is removed from the TSD.

If the TSD display is switched off, the camera image will be automatically displayed when reverse gear is selected. When

reverse gear is deselected and the 10 second period has expired, the TSD will revert back to its switched off state.

Component Description

PARKING AID

Two levels of parking aid system can be fitted; a rear only system or a front and rear system.

The parking aid system provides an audible warning to the driver when any obstacles are in the path of the vehicle during forward (if front sensors are fitted) or reverse parking manoeuvres. The system consists of four ultrasonic sensors in each bumper, a parking aid module and a parking aid switch.

At low speeds, the parking aid module uses the ultrasonic sensors to monitor the area around the front and rear bumpers. If an object is detected within a monitored area, the module then outputs a warning using the audio system speakers. The sensors can detect solid objects such as posts, walls and other vehicles and can also detect less solid objects such as a wire mesh fence. Objects very close to the ground may not be detected, but because of their low height may not cause damage to the vehicle.

The parking aid system comprises the following components:

- Parking aid module
- Parking aid switch
- Eight parking aid sensors.

The parking aid module communicates via the medium speed [CAN](#) bus with the audio system via the integrated audio module. The audio system then outputs the applicable warning tones from the front or rear speakers when an object is detected. The medium speed [CAN](#) bus is also used to collect vehicle data from other vehicle systems.

Parking Aid Module

The parking aid module is located on the [LH](#) side of the luggage compartment.

The parking aid module has three connectors which provide for power, ground and [CAN](#) bus connections, front parking aid sensors and rear parking aid sensors. The medium speed [CAN](#) bus connections provide for the receipt of the following information from other systems:

- [ABS \(anti-lock brake system\)](#) module - Road speed signal
- [TCM \(transmission control module\)](#) - Reverse gear engaged signal
- Trailer module - Trailer attached to vehicle
- Instrument cluster - Ambient temperature signal.

The module also outputs messages on the medium speed [CAN](#) bus which are received by the integrated audio module. The integrated audio module processes these messages and converts them into Media Orientated System Transport (MOST) signals which are passed to the audio system power amplifier. These signals are then used by the power amplifier to emit the applicable warning tones from the front or rear audio speakers when an object is detected by the front or rear parking aid sensors. A warning tone can also be emitted to alert the driver to a fault in the parking aid system.

The parking aid module performs self check routines and when the system is active checks the sensor wiring for short or open circuits. If a fault is detected a code is stored in a memory in the module and if necessary either the front and/or rear sensors can be disabled. The driver is made aware of any fault condition by the parking aid switch [LED](#) flashing and a continuous warning tone being emitted for 3 seconds, in place of the normal short tones when the system is functioning normally. Fault codes can be read using an approved Jaguar diagnostic system via the diagnostic socket.

Parking Aid Sensors

Four ultrasonic sensors are located in the front and rear bumpers. Each sensor comprises a sensor and a bumper insert. The insert ensures that each sensor is correctly orientated in relation to its location in the bumper.

Each sensor has a three pin connector which mates with a bumper harness, which in turn is connected to the main body harness. Three pins provide for power supply, ground and signal lines to and from the parking aid module.

Each sensor comprises a plastic housing which contains a piezo electric disc. The disc resonates at a frequency of 34.8kHz, producing the ultrasonic output. The disc also receives the reflected echo signal from any objects within range.

The parking aid module controls the operation of each sensor using a digital output on the signal line. The module controls the sensor in one of two modes; combined transmitter and receiver mode or receiver mode only.

Parking Aid Switch

E99386

The parking aid switch is located in the instrument panel switch pack, above the touch screen. The switch is the [LH](#) switch with an integral [LED](#).

The switch is a non-latching push switch which allows the driver to select the parking aid system on or off. When pressed, the switch momentarily connects a ground to the parking aid module.

The [LED](#) indicates when the parking aid system is active. The [LED](#) is controlled by the parking aid module. The switch allows the driver to disable the parking aid system when reverse gear is selected or to activate the parking sensors when not in reverse gear.

If a fault exists in the parking aid system, the [LED](#) flashes continuously when reverse gear is selected or the driver selects the parking sensors on, using the switch.

PARKING AID CAMERA

The parking aid camera is located on a bracket which is attached to the luggage compartment lid finisher.

The camera is connected to the vehicle harness by one 3 pin connector for the power, ground and [LIN](#) bus and a second connector for the video co-axial cable.

the camera produces color images to an analogue NTSC format, with a resolution of 640 x 480 pixels and an aspect ratio of 4:3.

The image captured by the camera is mirrored to give the driver a true representation of the rear view on the TSD.

Parking Aid - Parking Aid

Diagnosis and Testing

Principle of Operation

For a detailed description of the parking aid system, refer to the relevant Description and Operation section in the workshop manual. REFER to: (413-13 Parking Aid)

[Parking Aid](#) (Description and Operation),
[Parking Aid](#) (Description and Operation),
[Parking Aid](#) (Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage.

• **NOTE:** Particular attention should be paid to the following items where DTCs may not be logged:

- Check for contamination (e.g. dirt, grime, frosting, ice) around the parking aid sensors, if so refer to the parking aid section in the vehicle handbook.
- Check for the correct installation and alignment of the sensors to the bumper.
- Spurious detection of the ground may occur during front system operation on an up-slope, or down slope.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Sensor installation, alignment ● Sensor contamination 	<ul style="list-style-type: none"> ● Fuse(s) ● Relay(s) ● Wiring Harness ● Electrical connector(s) ● Front parking aid sensor(s) and holders ● Rear parking aid sensor(s) and holders ● Audio system ● Parking aid switch and LED ● Parking aid module

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00.

• **NOTE:** If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• **NOTE:** Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer approved diagnostic system).

• **NOTE:** When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places, and with an up-to-date calibration certificate. When testing resistance always take the resistance of the DMM leads into account.

• **NOTE:** Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• **NOTE:** Inspect connectors for signs of water ingress, and pins for damage and/or corrosion.

• **NOTE:** If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

• **NOTE:** When carrying out repair/diagnosis of the system, on removal of the front or rear bumper inspect the sensor connectors to ensure they were correctly latched and check fly leads for signs of chaffing or trapped wires.

Description and Operation

OVERVIEW

Mounted on the battery negative terminal is a battery monitoring system module. The battery monitoring system module is integral with the battery negative cable and is controlled by the [ECM \(engine control module\)](#).

CAUTION: To avoid damaging the battery monitoring system module, always use a suitable body ground point rather than the battery negative terminal when connecting a slave power supply to the vehicle.

If a new battery is fitted to the vehicle, the battery monitoring system module will require re-calibrating using the Jaguar approved diagnostic system.

Fitted on the battery positive terminal is a transit relay. The transit relay must be removed from the vehicle during the Pre-Delivery Inspection (PDI). For additional information, refer to the PDI Manual.

The vehicle battery provides power to the [BJB \(battery junction box\)](#). The [BJB](#) contains 3 megafuses, delivering power to the [RJB \(rear junction box\)](#), the [CJB \(central junction box\)](#) and the [EJB \(engine junction box\)](#). In addition to containing fuses and relays, the [RJB](#) and [RJB](#) contain software to control a number of vehicle systems. These functions are covered in the appropriate sections of this manual.

6	Instrument cluster
7	RJB (rear junction box)

System Operation

BATTERY MONITORING SYSTEM

Periodically the battery monitoring system module will instigate a self-calibration routine. To self calibrate, the battery monitoring system first charges the battery to its full condition.

• **NOTE:** If the vehicle is only driven for short periods the charging process could take a number of days to complete.

Once the battery is fully charged, the battery monitoring system will discharge the battery to approximately 75% of its full state of charge, but never lower than 12.2 V. The time taken to complete this part of the routine is dependent on the electrical load on the vehicle.

When the second part of the routine has been successfully completed, the battery monitoring system will return the battery to its optimum level of charge. The optimum level of charge will be between 12.6 V and 15 V, depending on battery condition, temperature and loading.

The battery monitoring system module also monitors the battery condition with the engine switched off. If a low voltage condition is detected the module can request the infotainment system is switched off to protect battery voltage. Once the infotainment system has been switched off, the vehicle must be run for at least 5 minutes to charge the battery before the infotainment system can be operated with the engine switched off.

Component Description

BATTERY

The battery is located under the floor in the **RH (right-hand)** side of the luggage compartment.

On new vehicles the battery positive terminal is fitted with a transit relay. The transit relay must be removed using the correct process detailed in the PDI manual.

The battery negative terminal is fitted with a battery monitoring system module. The module is integral with the battery negative cable and communicates with the **RJB** via a **LIN (local interconnect network)** bus connection. The battery condition information is passed to the **ECM** which controls the generator output accordingly.

CAUTION: To avoid damage to the battery monitoring system module, always use a suitable body ground point rather than the battery negative terminal when connecting a slave power supply. The recommended ground point is the spare wheel securing bracket in the luggage compartment.

Failure to use the recommended ground point will lead to the setting of a **DTC (diagnostic trouble code)**. Incorrect information of battery condition will be retained by the battery monitoring system module due to the unmonitored current flow into the battery. The system will however, recognize and compensate for the change in battery status after a period of time.

If a new battery is fitted, the battery monitoring system module will require re-calibration using a Jaguar approved diagnostic system. Replacement of the battery monitoring system module requires no action as the module will re-calibrate automatically.

BATTERY MONITORING SYSTEM

Battery Monitoring System Module

E98130

The battery monitoring system module measures battery current and voltage, which it communicates to the [RJB](#) over a [LIN](#) bus connection. The [RJB](#) transmits the battery information to the instrument cluster over the medium speed [CAN](#) ([controller area network](#)) bus. The instrument cluster acts as a gateway between the medium and high speed CAN bus networks, and transmits the battery condition information to the [ECM](#) over the high speed [CAN](#) bus. Based on the information received from the battery monitoring system module, the [ECM](#) will control the output from the generator and request the switching off of electrical loads if necessary. For additional information, refer to: For additional information, refer to:

Generator (414-02A, Description and Operation),
Generator (414-02B, Description and Operation),
[Generator](#) (414-02 Generator and Regulator - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

CAUTION: Due to the self-calibration routine, it is recommended that all power supply diagnostic testing is carried out using the Jaguar approved diagnostic system rather than a digital multimeter

The battery monitoring system module is able to generate [DTC](#)'s to help diagnose battery or generator power supply issues. These [DTC](#)'s can be read using the Jaguar approved diagnostic system. The Jaguar approved diagnostic system can also be used to implement a battery and generator self test routine. For additional information, refer to the Diagnosis and Testing section of the workshop manual.

If a fault is detected, the [ECM](#) will override the battery monitoring system module.

The battery monitoring system module [DTC](#)'s can be used to help diagnose battery or generator power supply faults. The [DTC](#)'s are stored in both the [RJB](#) and the [ECM](#). The Jaguar approved diagnostic system has a process for an automated power supply diagnostic procedure. The procedure provides a menu driven process to locate a fault in a logical sequence. The procedure uses the capability of the battery monitoring system and generator [LIN](#) bus controlled functions to provide current flow information and will detect if the battery monitoring system or generator are functioning correctly.

Battery, Mounting and Cables - Battery

Diagnosis and Testing

Principles of Operation

For a detailed description of the Battery, Mounting and Cables and charging system, refer to the relevant Description and Operation sections in the Workshop Manual. REFER to:

[Generator](#) (414-02 Generator and Regulator - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8, Description and Operation).

Inspection and Verification

CAUTION: Diagnosis by substitution from a donor vehicle is **NOT** acceptable. Substitution of control modules does not guarantee confirmation of a fault, and may also cause additional faults in the vehicle being tested and/or the donor vehicle.

1. 1. Verify the customer concern.
2. 2. Visually inspect for obvious signs of damage and system integrity.

Visual Inspection

Mechanical	Electrical
<ul style="list-style-type: none"> ● Front End Accessory Drive (FEAD) belt condition/tension ● Generator drive pulley 	<ul style="list-style-type: none"> ● Electrical connectors/pins ● Wiring harnesses

3. 3. If an obvious cause for an observed or reported concern is found, correct the cause (if possible) before proceeding to the next step.
4. 4. If the cause is not visually evident refer to the Symptom Chart, alternatively, check for Diagnostic Trouble Codes (DTCs) and refer to the DTC Index.

Symptom Chart

Symptom	Possible Cause	Action
Battery discharged	<ul style="list-style-type: none"> ● Charging/monitoring circuit fault ● Battery monitoring system failure ● Generator failure ● Battery failure ● Quiescent current high 	Carry out automated diagnostic routine using manufacturer approved diagnostic system
Generator not charging	<ul style="list-style-type: none"> ● Charging/monitoring circuit fault ● Generator failure ● Pulley loose/failure 	Carry out automated diagnostic routine using manufacturer approved diagnostic system

DTC Index

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

- NOTE: If a module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.
- NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give additional information read by the manufacturer-approved diagnostic system).
- NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.
- NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.
- NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may

be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B11D949	Vehicle Battery	<ul style="list-style-type: none"> ● Internal electronic failure. The battery monitoring module has detected an internal circuit failure ● Incorrect battery type or size installed ● High quiescent current ● A temporary battery state estimation error. The battery state estimation is performed by the battery monitoring system BMS ● Battery failure, worn out ● Battery damaged 	Check vehicle has correct battery type and size installed. Install new as required. Using manufacturer approved diagnostic system verify vehicle quiescent current draw levels are correct using power supply diagnostic function. Rectify as required. Using the Midtronics battery tester and battery care manual check the battery is serviceable. Install new as required. The BMS will correct a temporary battery state estimation error within a reasonable adaption time. The adaption time is dependant upon the driving time of the vehicle and may take a number of weeks.
B11DB01	Battery Monitoring Module	<ul style="list-style-type: none"> ● Battery monitoring system hardware fault 	Disconnect vehicle battery, re-connect after 60 seconds, clear DTC and retest. If DTC remains install a new battery monitoring module

Component Location

E93663

Generator and Regulator - 4.2L NA V8 - AJV8/4.2L SC V8 - AJV8 - Generator - Overview

Description and Operation

Overview

On 4.2L vehicles (naturally aspirated and supercharged), the charging system consists of a 130 A output generator and regulator assembly. The generator and regulator assembly generates electrical power for the vehicle electrical system and maintains the battery in a charged state.

When the engine is running the generator produces an alternating current, which is converted to a direct current internally. The output from the generator is controlled by the voltage regulator (located inside the generator) and then supplied to the battery through the main battery positive cable.

The generator is mounted on the front right side of the engine and driven at approximately 3 times engine speed by the accessory drive belt.

Refer to: Accessory Drive (303-05C, Description and Operation).

1	Battery monitoring system module
2	Battery
3	BJB (battery junction box)
4	Generator and regulator
5	ECM (engine control module)
6	Instrument cluster
7	RJB (rear junction box)

System Operation

General

The output voltage required from the generator and regulator is calculated by the battery monitoring system. Refer to: [Battery and Cables](#) (414-01 Battery, Mounting and Cables, Description and Operation).

The battery monitoring system signals the calculated voltage to the [ECM](#) via the [RJB](#) and the instrument cluster. The [ECM](#) then transmits the calculated voltage to the generator and regulator on the [LIN](#) bus connection.

The [ECM](#) will over-ride the voltage value requested by the battery monitoring system if it detects a fault in the generator and regulator. The [ECM](#) also signals the instrument cluster to display a warning message if it detects a fault with the generator and regulator. Refer to: [Instrument Cluster](#) (413-01 Instrument Cluster, Description and Operation).

Component Description

Generator and Regulator

The regulator provides a controlled variable voltage output from the generator. Two electrical terminals are provided on the outer casing of the generator. One terminal supplies the [DC \(direct current\)](#) voltage output from the generator to the battery positive terminal. The second terminal provides the [LIN](#) bus connection between the regulator and the [ECM](#).

U300281	Vehicle Identification Number	<ul style="list-style-type: none"> Vehicle/component mis-match. Corrupt VIN data being transmitted, suspect module previously installed to other vehicle 	Check and install original/new information and entertainment module as required, refer to the new module/component installation note at the top of the DTC Index

Audio Amplifier Module

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

If DTC remains carry out MOST tests and test USB cable for open, short circuit, clear DTC and re-test. If DTC remains suspect the portable audio interface module, check and install a new module as required, refer to the new module/component installation note at the top of the DTC Index
U300362	Battery Voltage	<ul style="list-style-type: none"> Mis-match in battery voltage, of 2 volts or more, between portable audio interface module and RJB 	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system

Digital Audio Broadcast Module

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.

DTC	Description	Possible Cause	Action
B11A411	L-Band Antenna	DAB L-Band antenna circuit - short to ground	If DTCs: B11A411, B11A511, U300044, U30004A, U300098, U300362 have logged at the same time with invalid snapshot data carry out a DTC clear and re-read to ensure the DTCs have not re-logged. If the DTC B11A411 does relog (without the other DTCs) carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to electrical circuit diagrams and check DAB L-Band antenna circuit for short to ground
B11A415	L-Band Antenna	DAB L-Band antenna circuit - short to power, open circuit	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to electrical circuit diagrams and check DAB L-Band antenna circuit for short to power, open circuit
B11A511	Band 3 Antenna	DAB Band 3 antenna circuit - short to ground	If DTCs: B11A411, B11A511, U300044, U30004A, U300098, U300362 have logged at the same time with invalid snapshot data carry out a DTC clear and re-read to ensure the DTCs have not re-logged. If the DTC B11A511 does relog (without the other DTCs) carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to electrical circuit diagrams and check DAB Band 3 antenna circuit for short to ground
B11A515	Band 3 Antenna	DAB Band 3 antenna circuit - short to power, open circuit	Carry out any pinpoint tests associated with this DTC using the manufacturer approved diagnostic system. Refer to electrical circuit diagrams and check DAB Band 3 antenna circuit for short to power, open circuit
U300004	Control Module	System internal failure	Clear the DTC and perform a system function check. If the DTC relogs and the system do not function correctly suspect the digital audio broadcast module. Check and install a new module as required
U300044	Control Module data memory failure	System internal failure	If DTCs: B11A411, B11A511, U300044, U30004A, U300098, U300362 have logged at the same time with invalid snapshot data carry out a DTC clear and re-read to ensure the DTCs have not re-logged.
U30004A	Control Module	Incorrect component installed	If the DTCs: B11A411, B11A511, U300044, U30004A, U300098, U300362 have logged at the same time with invalid snapshot data carry out a DTC clear and re-read to ensure the DTCs have not re-logged. If the DTC does re-log check/up-date Car Configuration File using manufacturer approved diagnostic system
U300055	Control Module	Incorrect Car Configuration File data received	Check/up-date Car Configuration File using manufacturer approved diagnostic system

DTC	Description	Possible Cause	Action
U300087	Control Module	Missing message	Check RJB for related DTCs and refer to relevant DTC Index. Check information and entertainment module for Car Configuration File and MOST network DTCs and refer to relevant DTC Index. Carry out MOST/CAN network tests using the manufacturer approved diagnostic system
U300098	Control Module	Component or system over temperature	If DTCs: B11A411, B11A511, U300044, U30004A, U300098, U300362 have logged at the same time with invalid snapshot data carry out a DTC clear and re-read to ensure the DTCs have not re-logged.
U300362	Battery Voltage	Mis-match in battery voltage, of 2 volts or more, between digital audio broadcast module and RJB	If DTCs: B11A411, B11A511, U300044, U30004A, U300098, U300362 have logged at the same time with invalid snapshot data carry out a DTC clear and re-read to ensure the DTCs have not re-logged. If only DTC U300362 is logged carry out any pinpoint tests associated with this DTC, check power supply circuits to Digital Audio Broadcast module and Rear Junction Box.

Integrated Control Panel

CAUTION: When probing connectors to take measurements in the course of the pinpoint tests, use the adaptor kit, part number 3548-1358-00

• NOTE: If the control module or a component is suspect and the vehicle remains under manufacturer warranty, refer to the Warranty Policy and Procedures manual (section B1.2), or determine if any prior approval programme is in operation, prior to the installation of a new module/component.

• NOTE: Generic scan tools may not read the codes listed, or may read only five digit codes. Match the five digits from the scan tool to the first five digits of the seven digit code listed to identify the fault (the last two digits give extra information read by the manufacturer-approved diagnostic system).

• NOTE: When performing voltage or resistance tests, always use a digital multimeter (DMM) accurate to three decimal places and with a current calibration certificate. When testing resistance, always take the resistance of the DMM leads into account.

• NOTE: Check and rectify basic faults before beginning diagnostic routines involving pinpoint tests.

• NOTE: If DTCs are recorded and, after performing the pinpoint tests, a fault is not present, an intermittent concern may be the cause. Always check for loose connections and corroded terminals.
